### Shock-like Symptoms and Hyperplasia of the Adrenal Glands in Rats during Long Term Administration of Histamine

SOME tumours of "non-endocrine" tissue can produce hyperplasia of the adrenal cortex and Cushing's syndrome. These changes could be a result of adrenocorticotrophic hormone (ACTH)-like action, produced by these tumours<sup>1</sup>.

Such tumours are, however, frequently localized in organs able to produce relatively large quantities of histamine, for example the lungs.

Could the histamine play a definite and detectable part in the complex of the above mentioned pathological relations? We have investigated the influence of long term administration of histamine on the adrenal glands in rats.

Fifty adult male Sprague-Dawley rats ( $300 \pm 20$  g body weight) were used in standard conditions. Twenty rats were injected subcutaneously with 0.05 ml. of starch gel daily (group I, control). Thirty rats were injected subcutaneously with 2 mg of histamine-2HCl in 0.05 ml. of starch gel daily (group II). The behaviour of the animals was observed during the experimental period. All the preparation of starch gel, 1 g of amylium tritici plus 15 ml. of 0.9 per cent sodium chloride were heated to form a gel.

Ten control and ten animals treated with histamine were decapitated on day 37 of the experiment. The other animals were decapitated on day 67. Adrenal glands and other endocrine organs were weighed and fixed in 10 per cent formalin. Slices 5 $\mu$  thick were stained with haematoxylin and eosin.

During the first 30 days both the control and the experimental animals showed no noticeable behavioural changes. Later the animals which had been injected with histamine showed steadily intensifying symptoms of posthistaminic shock in the form of anxiety and of rales during respiration. During the following days the symptoms of posthistaminic shock were further intensified; the animals injected with histamine showed severe dyspnoea and forced respiration. All these symptoms appeared 3-5 min after histamine injection and lasted for the next 5 min. Then the animals were reassured, washed themselves, drank water and took food. The severity of such a posthistaminic shock was changeable in individual animals. One rat showed extremely severe shock after daily histamine injection. From about day 40 of the experiment the volume of the abdomen in that rat steadily increased. An autopsy made on this rat on day 67 revealed an enormous tumour (70 g in weight) on the left kidney. A striking enlargement of the adrenals was also found (left adrenal 80 mg; right adrenal 60 mg). Histological examination of the tumour revealed cancer of the kidney of a nephroblastoma type. The adrenals showed great enlargement of the fascicular layer and an increased number of clear cells in the medulla.

Table 1 shows the weights of the adrenal glands in the control and in the experimental animals. After 36 days of histamine administration the adrenals were heavier by about 9 per cent in comparison with the weight of those glands in the controls. The difference was not, however, statistically significant. The weight of the adrenals in rats treated with histamine for 66 days was statistically greater than that in the control animals. Microscopic examination of the adrenals of rats treated with histamine for 36 as well as for 66 days revealed enlargement of the fascicular layer (Fig. 1).

It was found that 0.05 ml. of starch gel used for injection could be absorbed from the subcutaneous site within 24 h. A solution of histamine in such a gel was made in order to prolong absorption and action of histamine in the system of the rat. The daily injection of 2 mg of histamine seemed to be rather a physiological dose, for it has been calculated<sup>2</sup> that an adult rat can produce in its body as much as 2 mg of histamine in a day. The mechanism by which histamine produced the described histo-

logical changes and the shock-like symptoms remains quite obscure. The development of shock-like symptoms seems to be an opposite process in comparison with the known phenomenon of adaptation to histamine<sup>3</sup>.

It is difficult to judge whether the effect of histamine on the adrenal cortex is direct or indirect, through the stimulation of ACTH production by the pituitary gland. The posthistaminic shock as a cause of adrenocortical hypertrophy may also be doubtful, because detectable histological changes had appeared in the adrenal cortex before initial development of shock symptoms. Previous investigations on rats injected daily with 1.0 mg of histamine-2HCl in 0.05 ml. of starch gel for 23 consecutive days revealed enlargement of the glomerular layer in the adrenal cortex but no detectable weight change of that organ<sup>4</sup>.

According to Kahlson the histamine forming capacity promotes both normal and malignant growths<sup>5</sup>. Extracellular histamine in the form of "long-acting histamine" (an oily suspension of histamine dipicrate), however, failed to promote wound healing or collagen formation<sup>6</sup>. The development of kidney cancer in one rat out of twenty treated with histamine for 66 days must also remain unexplained. The typical changes in the adrenals of the rat with kidney cancer were comparable with the changes in the adrenals of all the rats treated with histamine, and thus this seems to suggest that the tumour is not spontaneous. Further investigations are in progress.

I thank Dr. A. Kurnatowski for his help in the histological evaluation of the tumour, and Mrs. M. Rurarz for her technical assistance.

### Possible Synergic Influence of ACTH and FSH on the Adrenal Cortex in Hypophysectomized-Gonadectomized Rats

THE gonadotrophic hormones may be non-specific growth factors for the adrenocortical cells, chiefly in the so called intermediary zone<sup>1</sup>. These hormones, however, failed, unlike ACTH, to stimulate maturation and transformation of adrenocortical cells.

Purified preparations of ACTH can have a diminished ability to stimulate an increase in the adrenal weight, the incidence of mitotic activity and lipid depletion of the zona fasciculata<sup>2</sup>. It is suggested that purification discards a pituitary substance which potentiates the influence of ACTH on the adrenal cortex. An increased urinary 17-KS output was found to be caused by human chorionic gonadotrophin (HCG) in a case of congenital adrenal hyperplasia<sup>3</sup>. A suggestion has been passed on that HCG can stimulate 17-KS excretion when secretion of ACTH is normal or augmented.

The results of simultaneous influence of ACTH (ACTH 'Polfa') and of pituitary gonadotrophin ('Glanduantin', Richter) on the adrenal cortex in hypophysectomized-gonadectomized rats are presented in this report. Eight normal and twenty hypophysectomized-gonadectomized male Sprague-Dawley rats (body weight  $200 \pm 20$  g) were used in standard conditions. From the fifth post-operative day for 24 consecutive days the urine was collected from the groups of normal and of hypophysectomized-gonadectomized animals treated with hormones, as in Table 1.

Table 1

	I(8) Normals	II(6) Controls	III(4) FSH (v)	IV(4) ACTH (v)	V(6) FSH + ACTH (v)
5 days	—	—	—	—	—
10 "	—	gel	2.5	0.05	2.5 + 0.05
5 "	—	"	5.0	0.1	5.0 + 0.1
4 "	—	"	2.5	1.0	2.5 + 1.0

Numbers of animals in parentheses. FSH, follicle stimulating hormone.

The hormones were injected subcutaneously once daily in 0.05 ml. of starch gel (1 g of amylium tritici plus 15 ml. of 0.9 per cent sodium chloride heated until gel formation). Solutions of the hormones in such a gel were used to prolong absorption and action of hormones in the system of the rat. Control animals were injected with the starch gel only. Excretion of 17-KS (Zimmermann's method) and of acid mucopolysaccharides (carbazole and orcinol methods) was determined. In decapitated hypophysectomized-gonadectomized animals a macroscopic inspection did not reveal pituitary remnants. This report gives the results of histological examination of the adrenal cortex and of 17-KS determination.

Fig. 1 shows that the greatest and statistically significant increase of the adrenal weight was found in rats treated with FSH and ACTH in comparison with all the other groups of hypophysectomized-gonadectomized animals ( $P < 0.05$ ).

Adrenal cortex of hypophysectomized-gonadectomized control animals (Fig. 2, II) showed marked atrophy of the fascicular layer with weakly denoted cellular borders and a broad intermediary zone of small acidophilic cells. Administration of FSH caused marked enlargement of the intermediary zone and detectable enlargement of the

Fig. 1. The weight of the adrenal glands in normal and in experimental rats. The figures at the bottom of columns denote number of animals.

glomerular layer (Fig. 2, III). Administration of both ACTH alone (Fig. 2, IV) or ACTH in combination with FSH (Fig. 2, V) caused clear zonal reconstruction of the adrenal cortex. All the cortical layers were built of well demarcated but significantly smaller cells than in the adrenal cortex of normal animals (Fig. 2, I).

The circadian values of urinary 17-KS in normal rats were 20–26  $\mu\text{g}/\text{animal}$  or 65–90  $\mu\text{g}/\text{four animals}$ . Hypophysectomy–gonadectomy caused deep decrease of 17-KS excretion within the first few days after the operations. Steady recovery of adrenocortical function in respect to excretion of 17-KS was then observed and from days 5–10 after the operation all the animals showed quite normal but still changeable excretion of 17-KS (41–87  $\mu\text{g}/\text{four rats}$ ). The highest stimulation of excretion of 17-KS (of more than 100 per cent) was found within the first 2 days of administration of ACTH in a dose of 0.1  $\mu$  daily. ACTH in combination with FSH did not cause detectable changes in excretion of 17-KS in comparison with the values in the control animals.

The ACTH and gonadotrophin used were not highly purified hormone preparations. Quite comparable changes in the adrenal cortex, however, had been observed previously<sup>1</sup> in hypophysectomized–gonadectomized rats treated with 'Glanduantin' or FSH-NIH-S1. Similar changes caused by 'Glanduantin' were reproduced in this experiment. The most striking histological feature of the adrenal cortex subjected to the action of gonadotrophin was enlargement of the intermediary zone. Such a zone could be present in normal rats and it seems to be dependent on the dietetic regimen given to the animals. According to Chester-Jones *et al.*<sup>4,5</sup> the presence of the intermediary zone in the adrenal cortex could be a consequence of starvation of rats. Nevertheless, hypophysectomy produces a broad sudanophobic zone in the adrenal cortex. The same is true for the adrenal cortex in hypophysectomized–gonadectomized rats.

Administration of small doses of ACTH caused clear normalization of zonal structure of the adrenal cortex, but there was only slight increase of weight of the adrenals. Concomitant administration of ACTH and pituitary gonadotrophin ('Glanduantin') caused not only normalization of zonal structure of the adrenal cortex, but also a statistically significant weight increase of that gland.

It seems probable that pituitary gonadotrophin of FSH type may be a non-specific growth factor for the adrenal cortex, especially for the cells situated on the

border between the glomerular and the fascicular layers. ACTH is a potent factor stimulating transformation of the adrenocortical cells, Gotschau's theory. Concomitant influence of both hormones on the adrenal cortex may be synergic from the morphological, if not from the histo-functional, standpoint.

### Early Effects of Hydrocortisone on Rapidly Labelled Rat Liver Ribonucleic Acids

ADMINISTRATION of single, large doses of hydrocortisone causes a marked increase in synthesis of rat liver RNA and the activity of several enzymes<sup>1</sup>. A direct gene action and enhanced synthesis of specific messenger RNAs has been suggested<sup>2</sup> and positive evidence for this hypothesis was presented<sup>3,4</sup>. In contrast, other experiments indicate that hydrocortisone provokes an unspecific stimulation of RNA synthesis<sup>5,6</sup>. In almost all the reported experiments, hydrocortisone was administered before injection of the labelled RNA precursors. In an attempt to elucidate the primary effects of hydrocortisone, we investigated the effects of administering this hormone after short term labelling of liver RNAs.

The experiments were carried out with male, albino rats of 100–150 g body weight. Carrier-free sodium phosphate labelled with phosphorus-32 (300  $\mu\text{C}/100 \text{ g}$ ) or orotic acid-6-<sup>14</sup>C (25  $\mu\text{C}/100 \text{ g}$ ; specific activity, 3.124  $\text{mc./mmole}$ ) was injected intraperitoneally, followed at different intervals by 10  $\text{mg}/100 \text{ g}$  of hydrocortisone. The animals were killed by decapitation and the livers were chilled in 0.14 molar sodium chloride. All subsequent operations were carried out at 4° C. A 10 per cent homogenate in 0.14 molar sodium chloride containing 0.05 per cent polyvinyl-sulphate (PVS) was prepared. The liver RNA fractions were obtained by the method of Georgiev and Mantiéva<sup>7</sup>, modified as follows: the homogenate was centrifuged at 600g for 5 min, the supernatant made 0.5 per cent with respect to sodium dodecyl sulphate (SDS) and deproteinized three times for 15 min, each time with phenol (saturated with 0.14 molar sodium chloride, pH, 5.0). RNA was precipitated from the last water phase with 2 volumes of ethanol containing 1 per cent potassium acetate. This fraction represented the bulk of the cellular RNA and is designated 'cytoplasmic RNA' (cRNA). The 600g sediment was extracted threefold with cold phenol: 0.14 molar sodium chloride (1 : 1) at 4° C and the resulting interphase layer was suspended in 0.14 molar sodium chloride containing 0.5 per cent SDS and 0.05 per cent PVS. An equal volume of phenol was added and the mixture was subjected to 40° C for 5 min. The cooled water phase was deproteinized twice and RNA was precipitated as already described. This fraction is designated 'nuclear R-RNA' (R-RNA). The interphase layer was extracted once with cold phenol: 0.14 molar sodium chloride at 4° C, then suspended in 0.14 molar sodium chloride (plus SDS and PVS) and treated with hot phenol at 65° C for 5 min. The RNA obtained from the water phase after three deproteinizations at 4° C is designated 'nuclear D-RNA' (D-RNA). The remaining interphase layer after this extraction contained only traces of RNA labelled with phosphorus-32. The different RNA fractions were washed with ethanol, dissolved in 0.01 molar sodium chloride and purified by gel filtration through 'Sephadex G-25' at 4° C (ref. 8). RNA was determined by its *O.D.*<sub>260</sub> and its radioactivity as cold 5 per cent trichloro-

Fig. 2. The adrenal cortex (I) of normal rat, and of hypophysectomized-gonadectomized rats; (II) control; (III) treated with FSH; (IV) treated with ACTH; and (V) treated with FSH plus ACTH. Stained with haematoxylin and eosin. ( $\times 100$ ).

acetic acid insoluble counts. Agar gel electrophoresis and subsequent autoradiography were carried out by the method of Tsanev *et al.*<sup>9,10</sup>. The mononucleotide composition of RNA after 18 h of hydrolysis with 0.5 normal potassium hydroxide at 37° C was performed according to Katz and Comb<sup>10</sup>. The radioactivity of the nucleotides was determined directly in solution with a 'Vakutronic' VA-Z-430 counter.

In preliminary experiments it was found that incorporation of inorganic phosphate into all three RNA fractions proceeds almost linearly up to 4 h. Administration of hydrocortisone causes a marked increase in their labelling as followed for 2-4 h after administration of the hormone. The results obtained with shorter periods of hydrocortisone action are given in Table 1.

Two hours after administration of hydrocortisone the specific activity of all RNA fractions is greater than that of the controls, but 60 min after administration of hydrocortisone the specific activity of both nuclear RNA fractions is less than in control animals, while that of the cytoplasmic RNA is slightly greater.

Determination of the labelling of the four RNA nucleotides showed that the observed variations of RNA labelling are inherent to all constituent nucleotides. Table 2 shows the mononucleotide composition of the three RNA fractions (direct determination) and of their rapidly labelled components (distribution of phosphorus-32). It should be pointed out that at both times after application of hydrocortisone (60 or 120 min) the mononucleotide composition of RNA remained essentially the same as in control animals, and therefore only mean values are given. These results agree with previous findings on the mononucleotide composition of RNAs from different sub-cellular fractions<sup>11</sup>.

The results of our experiments and those of others<sup>5,6</sup> clearly show that hydrocortisone provokes an unspecific stimulation of RNA synthesis, thus making unlikely a direct gene action of this hormone. The decreased labelling of nuclear RNA fractions, 60 min after hydrocortisone, is of particular interest. This effect is an early one, for a high concentration of hydrocortisone into rat liver was de-

Fig. 1. Electrophoretic pattern of rat liver nuclear RNAs isolated from animals killed 120 min after *in vivo* administration of orotic acid-6-<sup>14</sup>C (25  $\mu$ Ci/100 g of body weight). Agar gel electrophoretic fractionation for 100 min at 9 V/cm. Solid line, O.D.<sub>250</sub>; dotted line, relative radioactivity units obtained from the autoradiogram recorded at 550 m $\mu$ . A and B, Nuclear R-RNA; C and D, nuclear D-RNA. A and C, Control animals; B and D, animals treated with 10 mg/100 g of hydrocortisone 60 min before death. For further details see text.

tected 30 min after its administration<sup>12</sup>. There are two possible interpretations: (1) that hydrocortisone increases the rate of nucleo-cytoplasmic transfer of newly synthesized RNA and (2) that hydrocortisone brings about an accelerated degradation of rapidly labelled nuclear RNA. No markedly increased ribonuclease activity of nuclear chromatin is observed after hydrocortisone<sup>13</sup>, and so the first possibility is more acceptable.

Agar gel electrophoresis and autoradiography of the three RNA fractions give more information. In these conditions, the two ribosomal RNA peaks in cRNA display the same specific activity and hydrocortisone induces a parallel increase in their labelling as early as 60 min after application. The results obtained with the two nuclear fractions are shown in Fig. 1. The two nuclear fractions are complementary to one another to give the picture obtained with total nuclear RNA by sucrose density gradient centrifugation<sup>14</sup> and by agar gel electrophoresis<sup>8</sup>. There are the following peculiarities. (1) R-RNA gives the two ribosomal RNA fractions R<sub>1</sub> and R<sub>2</sub> which correspond to 28S and 18S ribosomal RNA. In most preparations, the ratio R<sub>1</sub>/R<sub>2</sub> is greater than that observed with cytoplasmic RNA. In addition, two slow moving fractions, A<sub>1</sub> and A<sub>2</sub>, are detected by their high labelling. In kinetic experiments (30-90 min) these fractions are the first to become labelled, followed by the R<sub>1</sub> peak<sup>8</sup>. (2) D-RNA shows a predominant R'<sub>2</sub> peak with a mobility corresponding to that of 18S RNA, as well as several slow moving fractions, A', which in this case, too, are the first to be labelled. In our conditions of extraction, sharp and well delimited peaks are observed, which indicates that the broad size distribution observed by others<sup>15</sup>, for a similar DNA-like RNA fraction, reflects its enzyme or thermal degradation rather than the expected size heterogeneity of messenger RNA.

Hydrocortisone (60 min after application) caused the labelling of the slow moving A and A' fractions to be relatively decreased, while that of R<sub>1</sub> in R-RNA and of R'<sub>1</sub> and R'<sub>2</sub> in D-RNA are markedly increased (Fig. 1, B and D). There is evidence<sup>15,16</sup> that the "heavy" nuclear RNA fractions are precursors of the 28S and 18S nuclear RNAs, and so our results can be interpreted to show that hydrocortisone causes a more rapid conversion of the precursor RNA molecules into the corresponding product RNAs.

Hydrocortisone provokes an unspecific stimulation of RNA synthesis in liver cells. Our results also suggest that

Table 1. EFFECT OF HYDROCORTISONE ON THE SHORT TERM INCORPORATION OF LABELLED PHOSPHATE INTO RAT LIVER RIBONUCLEIC ACIDS

Experiment	Time after (min)	Specific activity in c.p.m./mg of RNA			
		Phosphorus-32	Hydrocortisone	cRNA	R-RNA
(1)	90	-	180	1,641	3,640
	240	-	510	2,400	5,790
	240	120	572	2,885	6,670
(2)	150	-	1,100	9,860	10,950
	210	-	1,720	12,900	19,950
	210	60	1,940	9,650	18,070
(3)	120	-	355	2,450	3,800
	180	-	428	3,280	6,100
	180	60	486	2,300	5,250
	300	-	774	4,800	11,000
	300	120	865	6,200	14,850

Three rats are included in every group; each is injected intraperitoneally with 300  $\mu$ Ci of labelled phosphate and 10 mg of hydrocortisone/100 g of body weight. In control animals, hydrocortisone is omitted.

Table 2. EFFECT OF HYDROCORTISONE ON THE MONONUCLEOTIDE COMPOSITION OF TOTAL AND RAPIDLY LABELLED RAT LIVER RIBONUCLEIC ACIDS

Fraction	No. of experiments	Direct determination					Distribution of phosphorus-32				
		Molar ratio				GC	Molar ratio				GC
		A	U	G	C	AU	A	U	G	C	AU
cRNA controls	8	16.9	21.7	32.9	28.5	1.59	18.2	26.0	25.7	30.1	1.27*
plus hydrocortisone	8	17.5	21.0	32.3	29.2	1.60	16.6	26.5	27.5	29.4	1.32*
R-RNA controls	6	17.0	21.5	34.7	26.8	1.60	17.0	19.3	37.4	26.3	1.75
plus hydrocortisone	6	16.2	21.9	32.7	29.2	1.62	16.4	19.6	36.1	27.9	1.80
D-RNA controls	8	21.3	25.2	27.3	26.2	1.15	28.0	24.2	26.5	21.3	0.92
plus hydrocortisone	8	20.3	25.8	27.3	26.6	1.16	27.0	24.0	26.5	22.5	0.96

Mean values for 150-240 min after labelled phosphate, and 60-120 min after hydrocortisone, are given.

A, Adenylic acid; G, guanylic acid; U, uridylic acid; C, cytidylic acid. \* These values are too large, because no correction for terminal addition of cytidylic acid to soluble RNA was made.

hydrocortisone causes a more rapid nucleo-cytoplasmic transfer of RNAs, as well as an accelerated precursor-product conversion of nuclear RNAs.

### Relationship between Nuclear and Cytoplasmic RNA

Singh and Koppelman have subjected to mathematical analysis<sup>1,2</sup> some of the experiments carried out by my colleagues and myself on the relationship between nuclear and cytoplasmic RNA<sup>3,4</sup>. I have already demonstrated the inadequacy of the model presented by Singh and Koppelman in their first communication<sup>1</sup> by showing that a relationship defined by them as a constant ( $\lambda$  in my report) was in fact not a constant<sup>5</sup>. In their second communication<sup>2</sup>, Singh and Koppelman accept this point and present a modified version of the same exercise. As before, they seek to give the impression that they have taken the results of some of our experiments and shown that these results fit the particular mathematical model which they propose. Once again this is not so. In neither of the graphs produced by Singh and Koppelman have our results been accurately transcribed. In both instances, several points given in our original curves have been omitted from the graphs, and the curves have been truncated by deletion of early and late experimental points. This is well illustrated in the data for cytoplasmic RNA adenine shown in Fig. 1 of their communication. In our original report this curve is unequivocally sigmoid, but it appears in their communication as a straight line, an approximation which involves the omission of several

Fig. 1. Total amounts of radioactivity in cytoplasmic RNA adenine. The original graph from Harris *et al.* (ref. 4).

Fig. 2. The same graph as Fig. 1 re-plotted by Singh and Koppelman (ref. 2).

of our experimental points, the insertion of points which do not correspond to our experimental points and the deletion of the end of the curve. In order that readers may assess the extent of the transformation, I have reproduced in Fig. 1 the original experimental curve and in Fig. 2 the same curve as re-plotted by Singh and Koppelman.

It may have escaped the notice of some readers that the position initially adopted by Singh and Koppelman has undergone a change. The original point at issue between these authors and myself concerned the fate of the labelled nuclear RNA. My interpretation of our results was that much of this RNA underwent intracellular degradation. Singh and Koppelman took the view that this interpretation was incorrect. In their first communication<sup>1</sup> they stated: "Although the possibility of such degradation cannot be excluded, it appears from the analysis presented here that it does not occur to any significant extent". In a later communication, however, Singh<sup>6</sup> concluded that the nuclear RNA did contain a "labile fraction in high molecular weight RNA" and estimated that the "half-life time of the most labile component in nuclear RNA" was 20-30 min. In their second communication<sup>2</sup>, Singh and Koppelman state: "The deviation of experimental points from the straight line during the early period of incorporation is primarily due to the presence of low molecular weight RNA, which is known to undergo rapid turnover." (It should be noted that even our re-plotted curves fail to conform closely to their model; and no nuclear RNA was "known to undergo rapid turnover" until my colleagues and I revealed the fact<sup>7,8</sup>.) Again, later in the same letter: "Recent investigations (not yet published) suggest that such degradation is more prominent in non-growing cells." (With this I agree, and refer the authors to the papers by J. W. Watts and myself in 1959 in which the rapid turnover of nuclear RNA in a non-multiplying animal cell was described in some detail<sup>7,8</sup>.)

It thus appears that Singh and Koppelman do not any longer disagree with my view that much of the labelled nuclear RNA does undergo breakdown within the cell to end-products which are soluble in acid. That some nuclear RNA fractions might be precursors of stable cytoplasmic RNA is not, so far as I am aware, denied by anyone.

Singh and Koppelman<sup>1,2</sup> fit a kinetic model to data of Harris and Watts<sup>3</sup>. Their model depends on the equation

$$\frac{d}{dt}(a_{sc}) = \lambda(a_{sn} - a_{sc})$$

where  $\lambda$  is constant. But the data insist that  $\lambda$  is not constant: it changes by a factor of 3.5 during the course of the experiment. Singh and Koppelman<sup>2</sup> try to overcome the difficulty by approximating an exponential as a straight line. They do not succeed. Kinetic models based on erroneous assumptions are unacceptable. Any model which can satisfactorily fit the data of Harris and Watts must be rather more sophisticated than that of Singh and Koppelman.

## PATHOLOGY

### Premalignant Cells in Tumorigenesis induced by Plastic Film

PLASTIC material inserted under the skin of mice and certain other laboratory animals frequently leads to the formation of sarcomatous transplantable tumours<sup>1,2</sup>. This finding deserves consideration in view of the use of plastics in human surgery. It also attracts theoretical interest as an example of "physical" carcinogenesis. (The role of chemical cofactors is still under dispute although evidence is mounting against it<sup>3</sup>.)

Carcinogenic events are thought not to take place on the surface of the plastic insert but rather in connexion with the tissue capsule<sup>3</sup> which gradually builds up as a foreign body reaction. This communication presents evidence that 1-8 months before a tumour appears in mice, the premalignant cells are regularly found firmly attached to the insert itself where they seem to originate and mature. Premalignant cells could not be found in the capsule tissue except during the last 4 weeks before the appearance of palpable tumours.

Inbred mice (*CBA-T6*) at the age of 1.5-2 months received subcutaneous inserts in both flanks of double vinyl chloride acetate coverslips ('Dispo-slips') 15 × 22 mm in size. A control group (eighty animals) was left to itself. Tumours developed in 65 per cent of the male animals 9-12 months after operation, and in almost all the female animals after 7-12 months. In the experimental group, inserts and tissue capsules were cut in thirds after intervals of from 2 weeks to 12 months. One portion was left in the original animal. A second portion was used for histological, karyological and cultural examinations. The plastic and capsule pieces of the third portion were carefully separated and then individually transplanted into *CBA-H* recipient mice.

The results are shown in Table 1. No tumours developed in the original and the recipient animals when transplantation was carried out during the first 5 months after initial insertion of the plastic films. It is concluded that during this period premalignant cells either had not yet emerged or were unable to mature further outside the original film/capsule condition. The disturbance of the

primary processes at this time caused by removing two-thirds of the film and tissue capsule apparently stops tumorigenesis even in the original animal. (A separate control experiment has shown that pieces of plastic film one-third the size of the original inserts, that is, 7 × 15 mm, no longer cause tumours within 15 months; they are obviously below the threshold size critical for tumorigenesis.)

Tumours developed at the expected rate in the original and also in the recipient animals when the transplantation was carried out 6 or more months after the initial insertion of the plastic films. The tumours appeared simultaneously in the original and the corresponding recipient animals. The origin and identity of the tumours were established on the basis of the *T<sub>a</sub>*-marker chromosome. This indicates (1) that premalignant cells have emerged by the time of transplantation, (2) that premalignant cells are present in multiple foci, (3) that the population of premalignant cells is homogeneous with regard to the stage of development, and (4) that further maturation of premalignant cells towards the tumour occurs independently of the conditions of the film and capsule.

When the latent period (that is the time between transplantation and the appearance of the tumour) lasted 2-8 months, the tumours developed from transplanted film pieces only, not from capsule tissue. If the latent period happened to last 1 month or less, tumours developed in recipient animals from both the film piece and the capsule tissue. These results suggest that 2-8 months before the tumour appears the premalignant cells are firmly attached to the film and are not found in the surrounding capsule tissue. (It remains to be seen, however, whether premalignant cells in transplanted capsule tissue can be destroyed or returned to normality by the recipient animal in the absence of the piece of plastic film.) From the results available so far, it seems that tumorigenic cells detach from the plastic film and invade the capsule tissue only a few weeks before the growth of the tumour is recorded macroscopically. It can reasonably be assumed, therefore, that detachment of tumorigenic cells from the plastic film is actually one of the first manifestations of malignancy.

Apart from the experimental results described, it is suggested that this system allows the study of cell populations with a degree of premalignant maturation which can be determined accurately.

This investigation was supported by grants from the American Cancer Society, Inc., and the U.S. Public Health Service.

## BIOLOGY

### Probable Instance of Genetic Polymorphism in the Graptolites

A SPECIES, in the biological sense, is a community of individuals with a similar genetic structure, drawing on a common gene pool and having the ability to interbreed. Individual variation within such a community can be accounted for, in large part, by the segregation and recombination of genes according to Mendelian rules. This variation may be continuous and capable of being

expressed in terms of a unimodal distribution curve, or it may be discontinuous, with sharply contrasted differences which either do not overlap or else give rise to a bimodal (or multimodal) curve. Variation of the latter kind is polymorphism, and if the two or more distinct forms of a species co-exist in the same habitat, that is, if they are genetically determined rather than a product of geographical variation, this phenomenon can be called genetic polymorphism.

A genetically controlled variant may arise by the introduction of a new gene into the gene pool or through a new combination of existing genes. In either case, a relative and numerical increase of the variant in the community, brought about by a spread of the new gene or gene-combination by Mendelian inheritance, will be conditional on its conferring some selective advantage. If this requirement is fulfilled, the spread of the variant through the community will take place according to one of two patterns<sup>1</sup>. Polymorphism is said to be balanced when the spread of the advantageous character and the gene or genes controlling it is checked and held at some fixed level in the community due to environmental or genetic factors, or both. Transient polymorphism, on the other hand, is in operation only during the time taken for an advantageous gene to spread unhindered through the community; when the spread is complete, uniformity is reached once again, but of a new type from the old, and polymorphism is ended.

A probable case of transient polymorphism in the extinct planktonic graptolites (Class Graptolithina, Order Graptoloidea) is illustrated by the two "species" *Holmograptus lentus* (Törnquist) and *Nicholsonograptus fasciculatus* (Nicholson). The morphological resemblance between these two species is striking; indeed, the one important difference is the presence of two stipes in the rhabdosome of *H. lentus* (Figs. 4 and 5) as against a single stipe in *N. fasciculatus* (Figs. 1-3). Apart from this, there is similarity in thecal form, in the dimensions and form of the sicula (and, by implication, the siculozoid), in the position of the initial bud, and in the level at which stipe "1" (the only stipe in *N. fasciculatus*) leaves the sicula. Differences do exist, however, though these are probably not significant; thus the attitude of the proximal part of the single stipe relative to the sicula in *N. fasciculatus* varies beyond the limits observed in *H. lentus* and, moreover, the excessive distal recurving of the stipe in *N. fasciculatus* has never been recorded in *H. lentus*. These differences apart, the morphological resemblance between the two species is such that it is tempting

Fig. 4. *Holmograptus lentus* (Törnquist, 1911). Proximal end of rhabdosome. ( $\times 25$ .)

Fig. 5. *Holmograptus lentus* (Törnquist, 1911). Fragment of stipe. ( $\times 17$ .)

to attribute the alternative development of a bi- or unistiped rhabdosome to polymorphism.

In the graptolites, any variation in the number of stipes appears particularly abrupt because of the nature of the change involved; there is no intermediate stage between one stipe and two, even though one stipe may consist of but a single theca (as in *Peiragraptus* and *Parazygograptus*). In fact, in the case in point, the necessary change from two stipes to one could have been brought about by the suppression of a single bud. The graptolite colony is a kind of clone in which the first individual (the siculozoid) is thought to have been produced sexually while each subsequent member budded asexually from its predecessor; branching occurred when a pair of buds, instead of a single bud, was produced by one zooid. The mode of proximal end development in *H. lentus* accords with the simple *bifidus* type, involving a single crossing canal, and the non-appearance of stipe "2" would require merely a failure on the part of the first thecal zooid ( $th1^1$ ) to produce two buds, for if  $th1^1$  only gave rise to  $th2^1$ , and not to  $th1^2$  as well, stipe "2" could not develop. The resultant form would be that of *N. fasciculatus*. It seems reasonable to assume that not too remarkable an alteration in the genetic constitution of the siculozoid was necessary to effect the requisite change, particularly in view of the apparent ease with which the time of appearance of two buds and hence of two stipes could be varied in certain graptoloids.

Support for the suggested conspecificity of *H. lentus* and *N. fasciculatus* is provided by the extent of their common occurrence in space and time. In these respects, the well documented Swedish occurrences<sup>2,3</sup> are the most illuminating and suggest that polymorphism was of the transient kind, with ultimate replacement of the two-stiped by the one-stiped form. At Fågelsång, in Scania, *H. lentus* is confined to the zone of *Didymograptus bifidus* and it is stated to be of common occurrence throughout the zone<sup>2</sup>. On the other hand, *N. fasciculatus* (= *Azygograptus falciformis* Ekström) does not appear until some distance above the base of the *bifidus* zone and it occurs sparsely at first but then abundantly<sup>2</sup>; moreover, it has been shown that this form persists into the lower part of the *Didymograptus murchisoni* zone and thus into younger levels than *H. lentus*<sup>3</sup>. In Norway also, *N. fasciculatus* has been recorded (as *Azygograptus* sp.) from the lowermost part of the *murchisoni* zone<sup>4</sup>.

Elsewhere, the stratigraphical control is less precise, though in China *N. fasciculatus* occurs abundantly in the upper part of the zone of *Amplexograptus confertus*

Figs. 1-3. *Nicholsonograptus fasciculatus* (Nicholson, 1869). Three proximal ends showing the variable attitude of the stipe relative to the sicula (1,  $\times 15$ ; 2,  $\times 19$ ; 3,  $\times 18$ ).

or the highest of three sub-zones<sup>5</sup>. *Holmograptus lentus* (= *Tylograptus geniculiformis* Mu) appears earlier, probably in the highest part of the *Didymograptus hirundo* zone, and ranges through the *confertus* zone<sup>6</sup>.

The facts suggest that the uniramous variant was endowed with some particular selective advantage which enabled it to spread rapidly through the community, ultimately replacing what had been the normal variant. What the particular advantage attached to a single as against a two-stiped rhabdosome was is uncertain, particularly in view of the popularity of the bilaterally symmetrical rhabdosome among Ordovician graptoloids; however, it is possible that the uniramous condition was merely a secondary side-effect (in itself having no particular advantage) and the primary direct effect to which it was related may have been physiological.

With regard to taxonomy, both variants should be denoted by the same name—*fasciculatus*, because it has priority over *lentus*—if the relationship suggested here is the correct one. The recognition of two (morphological) species does, however, seem a necessary concession in this case, as the test of conspecificity is ability to interbreed, and in view of this requirement the suggested relationship must remain speculative. Separation of the two forms is also valuable from the stratigraphical standpoint. Moreover, if a distinction is to be drawn at the specific level it would seem advisable to adopt the same practice at the generic level, as the number of stipes in the rhabdosome is a primary taxobasis in the definition of graptoloid genera.

## Ionic Balance in the Crustacea

THE internal medium of the Crustacea varies in inorganic composition from species to species, but keeps at least a general resemblance to sea water. In one sense the composition is entirely determined by the environment and regulatory mechanisms of the species, but these mechanisms have presumably evolved so as to maintain the balance of ions close to an optimum for each physiological process. Although some of these conditions of optimum balance may vary between species, those that do not should reveal themselves through correlations among the levels of various ions. The aim here is to consider correlations among sodium, potassium and magnesium. There is known to be an inverse relationship between concentration of magnesium and activity in marine species caused, perhaps, by the depressant action of magnesium at the neuromuscular junction<sup>1</sup>.

Data on thirty-one marine, terrestrial and freshwater species of Malacostraca are shown in Table 1 as either mmol/l. of blood or mmol/kg of water; the difference is not significant in the present context. Through natural variation (for example, in relation to the moulting cycle<sup>2</sup>) and differences in analytical techniques some of these figures may be unrepresentative, particularly when based on single determinations. Those for calcium vary so little that significant correlations with those for the other cations cannot be demonstrated and, in any case, only part of the calcium may be ionized<sup>3</sup>. Concentrations of potassium, which in marine forms may be greater or smaller than in sea water, show a marked correlation with those of mag-

Fig. 1. Concentrations (mmoles) of potassium and values of the expression  $[Mg]([Na] + 400)/([Mg] + 7)$  for various Malacostraca and for sea water.

nesium (up to a concentration of magnesium of about 25 mmol/l) and also with sodium. These two relations are combined in Fig. 1 where values of [K] are shown plotted against those of the empirical expression  $[Mg]([Na] + 400)/([Mg] + 7)$ . The line through these points is such that  $[K] = \frac{0.0174 [Mg]([Na] + 400)}{([Mg] + 7)}$ . Another line corre-

sponding to sea water of salinities 2.0 per cent to 4.2 per cent is also shown and the points for Crustacea lie typically above it. This is, however, not achieved in the same way by each species, because concentrations of individual ions may be above or below those in sea water. Correction for variations in activity coefficients, particularly low for magnesium at the ionic strength of sea water, would

\* Personal communication from J. D. Robertson.

change the constants in the equation but probably have little effect on the goodness of fit.

The interpretation of correlations is very difficult and, in this instance, can only accompany the recognition of some physiological process that is affected by cations in a manner reconcilable with these particular relations. A possible clue, however, is obtained when the above equation is rewritten in the following form:

$$\frac{(1 + 1/n)[K]}{([K] + 0.0174[Na]/n + 7/n)} = \frac{[Mg]}{([Mg] + 7/(n + 1))}$$

where  $n$  is any number. If, for example,  $n = 7$ , then

$$\frac{1.14[K]}{([K] + 0.0025[Na] + 1.00)} = \frac{[Mg]}{([Mg] + 0.875)}$$

Such an expression could apply if the optimum composition of the extracellular fluid were such that some surface adsorbed potassium and magnesium from it in definite proportions; the sites for the adsorption of the two ions on this view would differ, but sodium would be competing for the potassium sites. These potassium sites could conceivably be those on ATPase which is activated by magnesium and sodium and which is involved in the active transport of sodium and potassium across cell membranes<sup>16</sup>.

### Association of *Xanthomonas sesami* with Two Types of Leaf Spots affecting Sesame

SESAME (*Sesamum orientale* L.) grown under rain-cultivation in the Sudan is severely affected by two types of leaf spotting. In one (Fig. 1) the spots are usually small, 2–4 mm in diameter, dark red-brown to black in colour, somewhat translucent, often angular with sharply defined margins, and may coalesce to form irregular lesions. The dead tissue of the spot later dries up and becomes brittle. In the other type (Fig. 2) the spots are large, 4–14 mm in diameter or more, greyish or light brown, usually opaque with somewhat diffuse margins, often irregular and frequently coalescing. Affected tissues become wrinkled before they dry. The first type is more often found towards the top of the plant while the second type is more frequently encountered towards the base.

Sabet and Dowson<sup>1</sup> attributed the first type of spots (dark brown spots) to a new species of *Xanthomonas*, namely, *X. sesami*. They considered the second type (light brown) to be a result of some physiological causes, possibly rain damage following waterlogging of the tissues. Rao<sup>2</sup> in India, dealing with what appears to be the light brown spot type, attributed the disease to a distinct strain of *X. sesami*. The cause of the light or grey brown spot type and its relation to the dark brown type are examined in the present communication.

The methods used for isolation, inoculation and characterization of the causal bacteria were those described by Sabet and Dowson<sup>1</sup>. Isolations were made from leaves which showed each of the two types of symptoms separ-

Fig. 1

Fig. 1. Sesame half-leaf showing dark brown spots ( $\times c. 1.3$ ).

Fig. 2

Fig. 2. Sesame half-leaf showing light brown spots ( $\times c. 1.3$ ).

ately. Two isolates of suspected *Xanthomonas* were obtained from each type. Bacterial suspensions for inoculation were prepared from 72 h old cultures grown on yeast extract-glucose agar. They were sprayed on field grown sesame planted in small well separated patches of about twenty plants each (potted sesame plants were somewhat chlorotic, stunted and unsuitable for inoculation). The plants of each patch were covered with polyethylene sacs and shaded for 72 h. Control plants were sprayed with tap water.

Two series of inoculation experiments were carried out during the periods December 1964–February 1965 and August–October 1965 inclusive. Three inoculation experiments were made in each series using plants 3–4, 6–8 and 10–12 weeks old, respectively. In each case two isolates (one from dark brown spots and the other from light brown spots) were used for inoculation.

The bacteria isolated from the two types of spots proved to be indistinguishable from each other in morphological, cultural and biochemical characters. They agreed in every respect with *Xanthomonas sesami* Sabet and Dowson<sup>1</sup> and are identified as such.

Under prevailing experimental conditions, the four isolates produced the first spot type, that is, dark brown, sharply defined, rather small spots. These spots developed readily on the younger leaves near the top of the plants. They also appeared on the capsules when these had already developed at the time of inoculation. The other type of spots (light brown) could not be reproduced by any of the isolates used, even those which were originally obtained from it.

Thus it is evident that the two types of sesame leaf spot described here are associated with infection by *X. sesami*. The dark brown type seems to be readily reproduced under a wide range of environmental conditions, at least those prevailing in Khartoum as well as in the central rainlands. The conditions which favour the development of the light brown spot type are not known.

These spots do not develop on the top leaves of the plant, yet it has not been possible to reproduce them, by repeated inoculations, on the lower leaves. This suggests that the effect of leaf position is an indirect one. It is possible that the high atmospheric humidity and high rainfall in the central rainlands favour the development of the grey-brown spot type, particularly on the lower leaves, which are more subjected to rain splashes. This spot type does not appear under the drier conditions of Khartoum. Sabet<sup>3</sup> has previously reported a similar instance in which mahogany leaf spots caused by *X. khayae* are small and dry in the Khartoum area, but large, with broad, dark green wet-shining margins in the central rainlands.

It is unlikely that the two spot types are produced by two distinct strains since isolates from the two types produce one type of spots under similar conditions. It is concluded that they are caused by one strain of *Xanthomonas sesami*. The dark brown type develops readily under a wide range of environmental conditions. Development of the light brown type requires a more exacting environment, possibly high atmospheric humidity and rainfall.

### Selective Nitrogen Assimilation by *Poria weirii*

SOIL under a stand of *Alnus rubra* Bong. in mixture with conifers was found to contain markedly higher levels of nitrate nitrogen than soil under an adjacent stand of pure conifers<sup>1</sup>. This phenomenon has substantial implications for the ecology of root pathogens and their antagonists in forest soils. We were particularly interested in *Poria weirii* Murr., a severely damaging pathogen of conifer roots in western North America, and we have therefore investigated its ability to assimilate nitrate nitrogen.

Many fungi, including Basidiomycetes such as *Collybia tuberosa* (Fr.) Quél. and *Lentinus tigrinus* Fr., can use nitrate nitrogen<sup>2,3</sup> and therefore presumably produce nitrate reductase, the enzyme required for reduction of nitrate to usable ammonium. Other fungi, however, cannot use nitrate nitrogen, for example, *Armillaria mellea* (Vahl. ex Fr.) Kummer<sup>4</sup>, many other higher Basidiomycetes<sup>5-8</sup>, and members of the Saprolegniaceae<sup>9</sup> and Blastocladiaceae<sup>3</sup>. *Streptomyces* species, notable among the organisms likely to antagonize *P. weirii*, commonly thrive on nitrate as a nitrogen source<sup>10-13</sup>.

Experiments were designed to determine (a) the relative growth of *P. weirii* when supplied respectively with nitrogen equivalents in nitrate, ammonium, or amino forms; and (b) whether *P. weirii* produces nitrate reductase.

*Poria weirii* was grown on Jennison's<sup>7</sup> liquid medium with potassium nitrate, ammonium chloride, and asparagine, as respective sources of nitrogen. Each form of nitrogen was included at each of three concentrations, corresponding to 10, 100, and 1,000 p.p.m. nitrogen in the medium. In each case four replicate flasks were inoculated with 4 mm agar disks cut from margins of colonies of *P. weirii* growing on malt agar. Cultures were grown for 40 days at room temperature (24°-28° C), after which the mycelial mats were collected, dried overnight at 105° C and weighed.

The procedure for extraction of nitrate reductase was essentially that devised by Nason and Evans<sup>14</sup>; the enzyme activity of the cell-free extract was determined by the colorimetric test for nitrite. At the beginning of the experiment (zero time) 0.05 ml. enzyme extract was added to give a final volume of 0.5 ml. containing 0.1 ml. of 0.1 molar potassium nitrate, 0.05 ml. of 2.6 × 10<sup>-3</sup>

molar flavin adenine dinucleotide (FAD), 0.04 ml. of 2.0 × 10<sup>-3</sup> molar reduced diphosphopyridine nucleotide (DPNH) and 0.26 ml. of 0.2 molar pyrophosphate buffer, at pH 7.0. After incubation for 20 min at 26° C, 0.9 ml. of water and 0.5 ml. of sulphanilamide reagent were added to stop the reaction, followed by 0.5 ml. of *N*-(1-naphthyl) ethylenediamine reagent to develop the colour. After 20 min, the optical density was read on a colorimeter at 540 mμ. Control tubes lacking DPNH were used to correct for turbidity caused by the enzyme. A fungus known to produce nitrate reductase, *Neurospora crassa*, was used to check the technique.

Table 1. MEAN DRY WEIGHT OF MYCELIUM OF *Poria weirii* GROWN IN SYNTHETIC MEDIA CONTAINING VARIOUS SOURCES OF NITROGEN\*

Nitrogen (ppm)	Potassium nitrate (mg)	Source Ammonium chloride (mg)	Asparagine (mg)
10	2.55	17.75	20.33
100	2.00	32.00	32.48
1,000	1.28	37.23	40.08

\* Mean of four replicates.

Table 2. NITRATE REDUCTASE ACTIVITY OF *Neurospora crassa* AND *Poria weirii*

Reagent	(ml.)	Addition (ml.)	(ml.)	(ml.)
0.1 molar KNO <sub>3</sub>	0.10	0.10	0.10	0.10
2.6 × 10 <sup>-3</sup> molar FAD	0.05	0.05	0.05	0.05
2.0 × 10 <sup>-3</sup> molar DPNH	0.04	0.04	0.04	0.04
0.2 molar pyrophosphate, pH 7.0	0.26	0.26	0.26	0.26
Enzyme extract	0.05	0.10	0.15	0.20
Water	0.90	0.85	0.80	0.75
<i>O.D.</i> at 540 mμ for <i>N. crassa</i>	0.01	0.03	0.05	0.06
Nitrite formed for <i>N. crassa</i>	1 × 10 <sup>-3</sup> μmole	2.5 × 10 <sup>-3</sup> μmole	3.0 × 10 <sup>-3</sup> μmole	4.5 × 10 <sup>-3</sup> μmole
<i>O.D.</i> at 540 mμ for <i>P. weirii</i>	0	0	0	0
Nitrite formed for <i>P. weirii</i>	0	0	0	0

*Poria weirii* did not use nitrate as a nitrogen source but grew well with ammonium or amino nitrogen (Table 1). Its behaviour in culture was markedly similar to that reported for *Armillaria mellea*<sup>4</sup>, another serious destroyer of tree roots. Moreover, the cell-free extracts of *P. weirii* completely lacked nitrate reductase activity (Table 2).

The high nitrate content of the soils under the stand with *Alnus rubra* appears disadvantageous to *P. weirii*: it cannot use nitrate nitrogen but antagonists such as *Streptomyces* spp. can. On the basis of these results and those of other investigations of this biological complex which are now in progress, we tentatively conclude that *Alnus rubra* mixed with conifers has a potential in the biological control of *P. weirii* and probably other pathogens on many sites of the Douglas fir region.

## GENETICS

## Criminal Behaviour and the XYY Male

IN 1965, Jacobs *et al.* published their preliminary findings of a chromosome survey conducted at a maximum security hospital, The State Hospital, Lanarkshire, Scotland<sup>1</sup>. The most remarkable finding in the completed survey was the discovery among 315 men of nine patients with an XYY sex chromosome constitution. Their behaviour, together with their pattern of crime, has now been closely studied. The full clinical details of this investigation will be published elsewhere by us, and this communication directs attention to the ways in which the XYY males differ from males with an XY sex chromosome complement at the same hospital.

All the patients admitted to this hospital have severely disordered personalities and they have been classified according to whether the cause is known or not. For example, some have brain damage which followed infections, others are epileptics, and others suffer from a psychosis. The largest group of patients have no known cause for their personality disorders. All the men with an XYY complement were classified in this category and eighteen other men have been randomly selected from this group for comparison with the nine XYY males. Seventeen of the eighteen control males were known to have an XY sex chromosome complement, the remaining being one of twenty-seven who had not been willing to be investigated when the chromosome survey was carried out.

There are three ways in which the XYY males differed importantly from the controls. First, although the patients in the two groups have penal records of comparable length, those of the XYY males include considerably fewer crimes of violence against persons. Thus, the nine XYY males had been convicted on a total of ninety-two occasions, but only eight of these convictions (8.7 per cent) had been for crimes against the person, while eighty-one (88.0 per cent) had been for crimes against property. In contrast, the eighteen control males had been convicted on 210 occasions, and forty-six of these (21.9 per cent) had been for crimes against the person while 132 (62.9 per cent) had been for crimes against property. Second, the disturbed behaviour of the XYY patients showed itself at an earlier age. This is reflected in a mean age at first conviction of 13.1 yr, compared with a mean age of 18 yr for the control patients, a difference which is significant at the 5 per cent level. Third, in the families of these patients the incidence of crime among the siblings of the XYY patients is significantly less than among those of the control patients. Thus, only one conviction is recorded among thirty-one sibs of the XYY patients while no less than 139 convictions are recorded for twelve of sixty-three sibs of the control patients.

The distribution of intelligence quotient among the XYY males probably reflected the distribution among the patients of the hospital as a whole. Seven were considered to be mentally sub-normal, but it is worth noting that the pattern of behaviour among the two whose intelligence quotients were not unusually low conformed with those of the other seven.

The picture of the XYY males that emerges from examination of those detained at the State Hospital is of highly irresponsible and immature individuals whose waywardness causes concern at a very early age. It is generally evident that the family background is not responsible for their behaviour. They soon come into conflict with the law, their criminal activities being aimed mainly against property, although they are capable of violence against persons if frustrated or antagonized. Their failure to respond to corrective measures leads to a sentence of prolonged detention in safe custody at an earlier age than is usual for offences of this kind. All nine men with an

XYY chromosome complement conform fairly closely to this broad description and it seems reasonable to suggest that their antisocial behaviour is due to the extra Y chromosome.

We thank Dr. R. P. Brittain and Dr. W. M. Court Brown for help, and Mr. Peter Smith for statistical advice.

### Microgeographical and Ecological Distribution of Colour Morphs of *Botryllus schlosseri* (Asciidiacea)

*Botryllus schlosseri* (Pallas), a compound ascidian widely distributed on European and western Atlantic coasts, is well known for its colour polymorphism, which has been shown to be under genetic control<sup>1-4</sup>. In the Venetian Lagoon *Botryllus* is found chiefly in two typical biotopes: the piles marking the navigable canals which cross the Lagoon, and the beds of *Zostera* which cover its bottom.

A colony of *Botryllus*, founded by a larva, grows by budding up to hundreds and thousands of zooids. Its life cycle consists of a long series of blastogenic generations which at a temperature of 18° C succeed each other at a rate of one a week<sup>5</sup>. Sexual reproduction in the Lagoon starts in April and continues until November. The new colonies in their turn reach sexual maturity in 1 or 2 months, and so several generations co-exist, reproducing at the same time. Like most other ascidians *Botryllus* is hermaphrodite, but, because the ripening of spermatozoa is somewhat delayed in comparison with the ripening of eggs<sup>6</sup>, selfing does not occur in the presence of spermatozoa from other colonies. Fertilization of eggs and development take place inside the zooids, and free-swimming larvae are liberated; these settle down and metamorphose within a few hours.

We collected colonies of *Botryllus* in two areas of the Lagoon, Venice and Chioggia, about 20 km apart, from two piles stations in Venice and from a single piles station and a *Zostera* station in Chioggia. The two stations in each area were about 1,300 m apart. The colonies on the beds of *Zostera* were collected at an average depth of 2.5 m and those on the piles from this same depth up to the surface. Samples from each station were collected in March and July 1964, the March samples accounting for the composition of the population after wintering and those of July including also the first generations of the new year.

The colonies were classified in the laboratory according to the presence or the absence in the zooids of (a) orange pigment and (b) an intersiphonal double band. These are genetic characters controlled by two independent genes<sup>1-4</sup>, both with an allele for the presence of the character dominating over an allele for the absence. A total of 2,587 colonies were examined; their distribution in the samples taken from the different stations and the frequencies of one of the phenotypes related to either gene considered are reported in Table 1.

The  $\chi^2$  test by the Brandt and Snedecor method was used for the statistical analysis of the samples. The results, which are given in Table 2, may be summarized as follows: (1) the two samples from each station do not differ significantly in either character; (2) the same is true of the animals taken from the two piles stations in Venice, whereas those sampled from the two stations, the

piles station and the *Zostera* station, in Chioggia, show highly significant differences; (3) the two groups of animals sampled from the piles in Venice and Chioggia respectively differ significantly in the frequency of the "orange pigment" character.

The conclusion may be drawn that the population of *Botryllus schlosseri* in the Venetian Lagoon is subdivided into sub-populations significantly different in the frequencies of genetically controlled colour morphs. Evidence has been given of the presence of microgeographical sub-populations living on the same biotope, the piles, in two areas about 20 km apart and of ecological sub-populations living in the same area on two different biotopes, the piles and the *Zostera* beds. At least as far as the sub-populations of the same area are concerned, their differences are likely to depend on the characters, which we have considered, exhibiting different adaptive values in the two biotopes.

## HAEMATOLOGY

### Evidence for Facilitated Diffusion of Anion in Erythrocytes

THE suggestion has been made by various authors<sup>1</sup> that anions as well as various non-electrolytes cross the membrane of erythrocytes by a special mechanism. An investigation of the permeability of human and rabbit

erythrocytes to ammonium chloride was carried out which suggested that the anion exchange in the erythrocyte of these two species involved facilitated diffusion (Hunter, F. R., and Ospina, B., unpublished results). The disadvantage of using ammonium chloride was that in addition to the movement of anions, ammonia also crosses the membrane<sup>2</sup>. Consequently, a less complicated system which involved only anion exchange was sought to test the conclusions reached with the ammonium chloride system.

There are several reports in the literature of volume changes of erythrocytes which result from the exchange of a monovalent for a divalent anion<sup>3-5</sup>. In the physiological exchange of chloride ion for bicarbonate ion across the erythrocyte membrane slight volume changes are expected as a result of a shift in the amount of base bound by haemoglobin with the associated slight change in pH (refs. 5 and 6). Much larger volume changes, however, would be expected if erythrocytes are placed, for example, in a solution of sodium sulphate. One sulphate ion will enter the cell for each two chloride ions that leave. Such an exchange should decrease the internal osmotic pressure of the cells and cause shrinkage<sup>4</sup>.

Parpart<sup>3,4</sup> mentioned that various substances, including butyl alcohol, decrease the rate of anion exchange. It has also been shown that tannic acid greatly increases the rate of anion exchange<sup>7,8</sup>. According to the interpretation of Hunter *et al.*<sup>9</sup> such a decrease in permeability in the presence of butanol and tannic acid indicates that facilitated diffusion is involved. Omachi<sup>10</sup> studied the effect of various metabolic inhibitors on the permeability of human erythrocytes to the sulphate ion and found a decrease in the rate at which this ion left these cells. He concluded, however, that his data could be reconciled with the suggestion of Passow<sup>11</sup> that the sulphate ion is "passively transported across the mammalian red cell membrane". A subsequent report<sup>12</sup> suggested that the regulation of anion permeability may depend on "biochemical processes resembling partial reactions in mitochondrial oxidative phosphorylation". For the foregoing reasons, a re-investigation of the exchange of sulphate for chloride ion across the erythrocyte membrane seemed of interest.

Human blood was obtained by venipuncture and citrated. Rabbit blood was obtained by cardiac puncture and heparinized. Both types of blood were washed three times with an isotonic sodium chloride solution buffered with phosphate to pH - 7.1. The cells were used immediately in most experiments although similar results were obtained with cells that were refrigerated overnight. Volume changes of the cells were measured at 30° C using a densimeter<sup>13</sup>. An aliquot (0.05 ml.) of washed cells was added to 10 ml. of 1/9 molar sodium sulphate buffered with tris buffer—pH - 7.5 in the chamber of the densimeter and a record of the shrinking of the cells was obtained. The effect of butanol and tannic acid on the rate of this volume change was studied. A 1 molar butanol solution in sodium sulphate solution was used throughout all the experiments. A fresh 100 mg tannic

acid in sodium sulphate solution was prepared each day. The time for half the total deflexion of each shrinking curve was measured. Experimental half-times were divided by control half-times to give relative times. Typical curves are shown in Fig. 1. A comparison of curves 1 and 2 and of 4 and 5 shows the decrease in the rate of shrinking with both types of erythrocytes in the presence of 0.1 molar butanol. The very marked inhibition in the presence of a low concentration of tannic acid is obvious from curves 3 and 6. All the data are summarized in Fig. 2. With human cells increasing concentrations of both butanol and tannic acid increase the relative times for shrinking which results from the exchange of sulphate for chloride ions. The tannic acid effect is about five times greater than that of butanol with the concentrations used. The inhibition in the presence of a single concentration of butanol and of tannic acid with rabbit cells can also be seen in the figure.

The rate of exchange of sulphate ion for chloride ion across the membrane of both human and rabbit erythrocytes is inhibited by butanol and markedly inhibited by

tannic acid. It has previously been postulated that such changes indicate facilitated diffusion<sup>9</sup>. Thus it is suggested that at least certain anions cross the membrane of the erythrocytes of some species by this mechanism.

The experiments were performed in the Department of Biology, University of the Andes, Bogotá, Colombia. We acknowledge a grant from the Rockefeller Foundation.

### Inhibitor of Glucose-6-phosphate Dehydrogenase Activity in the Erythrocytes of *Macaca nemestrina* Monkeys

DATA are available on the activity of G-6-P dehydrogenase in the erythrocytes of different species of monkeys<sup>1</sup>, using the dye decoloration method of Motulsky and Campbell<sup>2</sup>. In *M. nemestrina* the test did not clear after 5 h while in four other species the decoloration time was normal. We have further examined this phenomenon. Blood of seven individuals of *M. nemestrina*, seven *M. mulatta* and three *Presbytis entellus* in acid citrate dextrose inosine (ACDI) was examined. In agreement with earlier findings, *M. nemestrina* is the only species in this group which gave abnormal results. When fresh haemolysate ( $\pm 14$  g per cent) of *M. nemestrina* was used in the test instead of erythrocytes, some haemolysates cleared within normal time, others did not. In contrast, hundreds of normal human haemolysates gave normal results. Starch gel electrophoresis of the G-6-P dehydrogenase<sup>3</sup> showed a large amount of enzyme in all the monkey haemolysates, including those of *M. nemestrina* (Fig. 1). The mobility of the enzyme is similar to the fast-moving A type of human G-6-P dehydrogenase. Some factor must therefore have been present which prevented reduction of the dye in the test system, either by inhibition of the activity of G-6-P dehydrogenase or by continuous oxidation of the brilliant cresyl blue.

Ordinates, relative times for one-half the total deflexion. Left hand, butanol. Right hand, tannic acid.  $\circ$ , Human cells, butanol;  $\square$ , human cells, tannic acid;  $\bullet$ , rabbit cells, butanol;  $\blacksquare$ , rabbit cells, tannic acid.

Table 1. RESULTS OF BRILLIANT CRESYL BLUE DYE-DECOLORATION TEST\*

Test No.	Material tested	No. of tests performed	Clearance time (brilliant cresyl blue)
(1)	0.02 ml. of normal human whole blood in ACDI	15	All cleared within 1 h
(2)	0.02 ml. of normal human haemolysate	15	All cleared within 1 h
(3)	0.02 ml. of <i>M. nemestrina</i> whole blood in ACDI	7	All did not clear after 5 h
(4)	0.02 ml. of <i>M. nemestrina</i> haemolysate	7	Five cleared within 1 h and remained clear; one cleared within 1 h but turned blue again; one did not clear after 5 h
(5)	0.02 ml. of normal human whole blood in ACDI + 0.02 ml. of <i>M. nemestrina</i> whole blood in ACDI	10	All did not clear after 5 h
(6)	0.02 ml. of normal human haemolysate + 0.02 ml. of <i>M. nemestrina</i> whole blood in ACDI	7	All did not clear after 5 h
(7)	0.02 ml. of normal human haemolysate + 0.02 ml. of human whole blood in ACDI	4	All cleared within 1 h
(8)	0.02 ml. of normal human whole blood in ACDI + 0.02 ml. of <i>M. nemestrina</i> haemolysate	8	All cleared within 1 h, several turned blue again after 2-3 h

The test of Motulsky and Campbell was performed on material listed in Table 1. The right-hand column of Table 1 shows the decoloration time of brilliant cresyl blue. Tests 1 and 2 showed that the human whole blood and the human haemolysates had normal amounts of active G-6-P dehydrogenase; tests 5 and 6 showed that, although enough active G-6-P dehydrogenase was present in the test, the addition of blood of *M. nemestrina* prevented the decoloration of the dye, indicating the presence of an inhibitor in the monkey blood. When the same amount of *M. nemestrina* haemolysate was used rather than whole *M. nemestrina* blood, some samples cleared, others did not. Doubling the amount of substrate G-6-P in test 4 involving *M. nemestrina* haemolysate led to clearance of all tests within 1 h. This did not occur in tests with *M. nemestrina* whole blood. When *M. nemestrina* blood cells were separated from the plasma in ACDI, only the cells gave inhibition. The erythrocytes, further separated from the leucocytes and platelets, gave strong inhibition. Haemolysates did not always give inhibition; the inhibiting factor apparently is not in the haemolysate, but it can contaminate some haemolysates and is probably present in the erythrocyte membrane. Packed cells of *M. nemestrina* were washed, lysed with water and toluene and centrifuged; the clear haemolysate was carefully separated from the grey-white layer containing red cell membrane, leucocytes and platelets. This debris layer was washed in saline and dissolved in water. The haemolysate showed normal enzyme activity, whereas in those tests in which a small amount of debris was added, the test had not cleared after 5 h, showing that the inhibiting factor is in the debris. The same results were obtained when 0.2 ml. of membrane solution obtained by gradual haemolysis with cold water<sup>4</sup> (without the use of toluene) was added. This membrane solution contained about 30 mg dry weight/ml. Toluene in itself did not give inhibition.

To show that the failure of brilliant cresyl blue to clear was not caused by specific direct action of the factor on the dye, a test devised by Beutler<sup>5</sup> was used, in which an indicator is not added, and reduced triphosphopyridine nucleotide (TPNH) is demonstrated directly. In this test G-6-P is oxidized to 6-phosphogluconate and TPNH is reduced to TPNH. When activated with ultra-violet light, the reduced TPNH fluoresces brightly. Normal human whole blood or haemolysates gave bright fluorescence, and those of deficient individuals did not. Whole blood of *M. nemestrina* did not produce fluorescence in this test, but haemolysates carefully prepared to prevent contamination with membrane debris of red cells gave bright fluorescence. These results again indicate the presence of an inhibitor in whole blood of *M. nemestrina* not present in haemolysates. When erythrocyte mem-

brane solution was added to the reagent mixture before normal human blood was introduced, there was no fluorescence. When the membrane solution was introduced after normal human blood was added and after incubation, however, fluorescence did occur, showing that the inhibitor does not immediately eliminate the TPNH formed.

Although both the Motulsky and Campbell and the Beutler tests do not permit an accurate estimation of the inhibition of enzyme activity, we have shown that a strong inhibitor in the erythrocyte membrane of *M. nemestrina* monkeys was the cause of the abnormality of the dye decoloration test in this species. Some depressing action on G-6-P dehydrogenase of general nature in normal human red cell stroma was described by Carson *et al.*<sup>6</sup>

We thank Dr. E. Beutler for sending us his report of screening tests and for his valuable suggestions, Dr. T. H. Chen for providing blood from *P. entellus*, and Mrs. M. Scham and Mr. J. King for their technical assistance.

### Eosinophil Granulocytes and Hypoxia

ALTHOUGH the response of erythrocytes and their precursors to hypoxia has been extensively studied, much less is known of the changes in the leucocytes and their precursors. The presence of increased numbers of eosinophil granulocytes in the circulation of human subjects following exposure to hypoxia, however, has been noted<sup>1</sup>.

In the course of a quantitative study of blood and bone marrow in guinea-pigs exposed to hypoxia, striking changes in the numbers of eosinophil granulocytes were previously found in routine counts<sup>2</sup>. Results based on the small numbers of eosinophils encountered in routine differential counts of blood and bone marrow smears must, of course, be treated with a good deal of caution, and it seemed advisable to carry out further observations using a more accurate method. For this purpose three groups of guinea-pigs were studied, in which both the blood and bone marrow eosinophil levels were determined by direct haemocytometric methods after dilution of the marrow suspension or blood with a modification of Randolph's fluid; 150-200 eosinophils were counted on each occasion<sup>3</sup>. One group of six male guinea-pigs weighing 400 g each was placed in the decompression chamber and kept at general atmospheric pressure for 48 h. A similar group of six animals was exposed to a simulated altitude of 10,000 ft. for 48 h, while a third group of seven animals was exposed to a simulated altitude of 20,000 ft. for a similar period.

The results are summarized in Table 1. Placing the animals in the decompression chamber for a period of 48 h

Table 1. SUMMARY OF EOSINOPHIL COUNTS

	Control Group (A) (per mm <sup>3</sup> )	10,000 ft. Group (B) (per mm <sup>3</sup> )	20,000 ft. Group (C) (per mm <sup>3</sup> )	A v. B t (P)	A v. C t (P)
Blood	88 ± 44	59 ± 22	994 ± 516	1.4 (> 0.1)	4.3 (< 0.01)
Marrow	79,500 ± 16,000	86,700 ± 12,400	52,100 ± 6,300	0.9 (> 0.3)	4.2 (< 0.01)

±, S.D.

The *t* values are those of the standard error test for small samples, and *P* represents the probability of the value being exceeded in random sampling.

produced no apparent change in the numbers of blood and bone marrow eosinophils, the average values for these animals (column A) being within the normal limits<sup>4</sup>. There was also no significant change in eosinophil levels after exposure to hypoxia at an altitude-equivalent of 10,000 ft. At "20,000 ft.", however, there were highly significant changes both in blood and bone marrow eosinophils, the counts of the former being raised, those of the latter being lowered. It is tempting to speculate that these changes may be caused by crowding out of the eosinophil series from the bone marrow as a result of erythroid proliferation.

### Electrophoretic Haemoglobin Patterns in One Random Bred and Two Inbred Strains of Laboratory Rats

It has previously been shown by paper electrophoresis that two distinct electrophoretic types of haemoglobin, "single-spot" and "diffuse", occur in mice of several inbred strains and these have been proved to be under genetic control<sup>1,2</sup>. Rosa *et al.*<sup>3</sup> classified seven strains of mice into four different groups according to their haemoglobin patterns obtained by starch-gel electrophoresis. The largest number of bands observed was five<sup>3</sup>. Using starch-gel electrophoresis in a discontinuous buffer system, Morton<sup>4</sup> showed that the "diffuse" type of mouse haemoglobin separates into five bands. As far as electrophoretic investigations of haemoglobin in rats are concerned, we have not been able to find other published data except those by Giri and Pillai<sup>5</sup>. Using agar-gel electrophoresis they found that in the rat blood haemolysates two minor components of proteins were present in addition to one major component of haemoglobin.

The present experiments were conducted to determine whether or not the electrophoretic pattern of haemoglobin from rats of our stocks shows differences within and/or between the strains.

Haemoglobin from random bred albino, inbred Wistar and inbred black male and female adults was examined by starch-gel electrophoresis in a discontinuous buffer system. No animal studied was less than 3 months old. The random bred albino rats belonged to a local stock freely interbred for 35 yr and with no fresh blood introduced for the past 15 yr. The inbred Wistar rats belonged to the sixteenth filial generation of brother with sister matings starting from a pair of rats of the Wistar strain obtained from the Medical Faculty of the Zagreb University. The black rats belonged to the thirteenth filial generation of an accidental cross between a Wild-type

male and an albino female subsequently bred in our laboratory.

Blood samples were obtained by cardiac puncture and collected in tubes which contained heparin. The erythrocytes were washed seven times with isotonic saline at 4° C and lysed with 1 volume of ice-cold distilled water and a 0.2 volume of cold toluene. Stroma was precipitated by centrifugation in a Servall centrifuge for 30 min at 10,000 r.p.m., and the clear haemoglobin solution decanted and adjusted to the same concentration in all samples. Haemoglobin solution was kept at 4° C and used for analysis within one week after bleeding the animals. Samples were run as oxyhaemoglobin. The starch gels were prepared according to Smithies<sup>6</sup> and the discontinuous buffer system according to Morton<sup>4</sup> (tris-disodium-ethylenediamine tetraacetate dihydrate-citric acid and veronal buffer, pH 8.6, i.s. 0.05). Samples were run at 4° C for 16–18 h at 3 V/cm and 1 m.amp/cm. Gels were sliced and stained with benzidine.

The animals from the three strains used in the experiments could be classified into three different groups according to their haemoglobin pattern. Fig. 1 shows the separation of haemoglobin from animals of each strain. Haemoglobins from rats of the inbred Wistar and black strain were shown to be electrophoretically homogeneous within the populations, but they differed between themselves in respect to the mobility of bands. Within the random bred population of albino rats three types of electrophoretic haemoglobin pattern occurred, two of which proved to be identical with those of the Wistar and the black strain, respectively, and a third one which differed from both in the number of bands.

The three different haemoglobin patterns that we observed are presented schematically in Fig. 2. They are denoted as types I, II and III, and the bands marked 1–5. Two out of the three different patterns (types I and III) possess four bands each, three of which have equal mobility (bands 2, 4 and 5), whereas the fourth is located at position 3 in type I and at position 1 in type III. Electrophoretic type II contains five bands. In addition to the three bands which are common for types I and III (bands 2, 4 and 5), type II also shows the presence of one band absent in type I (band 1) and another one absent in type III (band 3). Table 1 is a summary of our results.

The results of the electrophoretic analyses of the same sample and of each individual pattern are reproducible.

Fig. 1. Starch-gel electrophoresis (Morton's discontinuous buffer system) of oxyhaemoglobins prepared from 4-month-old rats of random bred albino, inbred Wistar, and inbred black strain. A—Wistar male; B—black male; C, D, E—albino males; F—Wistar female; G—black female; H, I, J—albino females.

Fig. 2. Three types of the electrophoretic haemoglobin pattern observed in three strains of laboratory rat.

Table 1. ELECTROPHORETIC TYPES OF HAEMOGLOBIN IN THREE STRAINS OF LABORATORY RAT

Strain		No. of animals studied	Electrophoretic haemoglobin pattern		
			Type I	Type II	Type III
Albino random bred	Males	71	29	29	13
	Females	53	19	28	6
	Total	124	48	57	19
Wistar inbred	Males	8	8	0	0
	Females	15	15	0	0
	Total	23	23	0	0
Black inbred	Males	10	0	0	10
	Females	13	0	0	13
	Total	23	0	0	23

We believe that type II is a combination product of the other two.

## IMMUNOLOGY

### Coral Snake Venom: Antibody Response in Rabbits

CORAL snake venom is one of the most toxic venoms of American snakes<sup>1</sup>. Reports of coral snake bites in humans<sup>2,3</sup> suggest the venom acts as a neurotoxin causing paralysis of the respiratory muscles. Experiments in our laboratory indicate that coral snake venom produces neurotoxic effects in various species of animals.

Gitter *et al.*<sup>4,5</sup> found the neurotoxic components of viper venom poorly antigenic in the horse. Although the haemolytic components in large doses of venom were neutralized by horse antiserum produced against the venom, lethal concentrations of neurotoxins in the same venom doses were not neutralized by even the largest amounts of antiserum.

We now report a method for producing rabbit antiserum of high potency against the venom of the Eastern coral snake and an analysis of the venom antigens with antiserum by gel diffusion.

The same lot (1.6 g) of freeze-dried venom from the Eastern coral snake (*Micrurus fulvius fulvius*) (obtained from W. E. Haast, Miami Serpentarium Laboratories) was used in all experiments.

Zealand rabbits, weighing 2.4 kg each, were injected. The venom was dissolved in physiological saline and 1.0 ml. injected subcutaneously. Rabbits receiving up to 0.6 mg of venom remained free of overt symptoms. A dose of 1.0 mg produced flaccid paralysis. The condition of the paralysed rabbits did not improve in 48 h, so they were killed. Rabbits which received more than 1.0 mg of venom died after 16–20 h.

The  $LD_{50}$  for the venom in mice was determined by the method of Reed and Muench<sup>6</sup>. Six male albino mice which weighed 16–18 g were injected with 0.5 ml. intraperitoneally at each concentration of venom. Tests were considered completed in 48 h. The dose-response curve for the venom in mice is shown in Fig. 1. The  $LD_{50}$  is 13  $\mu$ g.

Six female New Zealand rabbits, weighing approximately 2.5 kg, were immunized according to the schedule shown in Fig. 2. The venom was dissolved in saline and filtered through a 'Millipore' type HA (0.45  $\mu$ ) filter. Equal volumes of the venom and 'Amphojel' (aluminium hydroxide gel) were mixed and 1.0 ml. of the mixture was injected subcutaneously. Each rabbit was bled weekly for 10 ml. from the marginal ear vein and the serum was recovered.

The rabbit sera were pooled and tested for potency by determining the number of mouse  $LD_{50}$  of venom the serum would neutralize. The method used was based on that of Keegan *et al.*<sup>7</sup>. Venom was diluted in saline to a concentration of 100  $\mu$ g/ml. (7.7 mouse  $LD_{50}$ ). Two-fold serum dilutions were made in saline. Equal volumes of diluted serum and venom were mixed and incubated for 1 h at 37° C. Precipitates which formed were removed by centrifugation; mice were injected intraperitoneally with 0.5 ml. of the supernatant fluids; and the number of  $LD_{50}$  neutralized by the antiserum was calculated.

The production of neutralizing antibody in rabbits is shown in Fig. 2. Neutralizing antibody was initially detected between the third and fourth week after the first injection of venom. The total amount of venom given over this period was 1.5 mg. The maximum amount of neutralizing antibody serum (38 mouse  $LD_{50}$  or 494  $\mu$ g of venom neutralized/ml.) was detected during the tenth week, 1 week after a booster injection of 1.0 mg. Although the booster injection produced a rapid increase in the amount of neutralizing antibody, the level reached was

Fig. 1. Dose-response relationship for Eastern coral snake venom in mice.

Fig. 2. Production of neutralizing antibody in rabbits immunized with Eastern coral snake venom.

not maintained for any significant period of time. The titre dropped abruptly after reaching the maximum concentration. We were unable to boost the level of antibody back to the maximum level once the titre dropped. Different combinations of rest periods and venom doses were tried, but only slight rises in the amount of neutralizing antibody were measured.

The maximum single dose of venom given to the rabbits during the course of immunization was 6.4 mg. The rabbit antiserum could neutralize at least 10 mouse  $LD_{50}$  of venom when the rabbits received this dose. Because the lethal dose for a 2.5 kg rabbit is approximately 1.0 mg, they tolerated a minimum of 6.4 rabbit  $LD$  at that time.

The venom was analysed for precipitating antigens by reacting it with the individual antisera from the six immunized rabbits. The sera were tested at the fourth, seventh and tenth weeks of immunization. This permitted an estimation of the time during the course of immunization when antibodies to different venom components were produced.

Gel-diffusion reactions were carried out in small Petri dishes. 10 ml. of 'Ion Agar No. 2' prepared in saline to a concentration of 1 per cent were dispensed per plate. The agar contained merthiolate in a final concentration of 1:10,000. A Feinberg gel cutter, No. 1801, was used to cut a pattern in the agar and the six rabbit sera were placed in the outside wells to react with the venom (100  $\mu$ g/ml.) in the centre well. Diffusion took place at 25° C for one week.

Photographs of the gel-diffusion reactions are shown in Fig. 3; a summary of the number of precipitin lines that formed is presented in Table 1. The number of precipitin lines ranged from one to four in the individual sera obtained from a specific bleeding. This demonstrates significant differences in the response of the individual rabbits to the components in the venom. There also were differences in the number of lines that formed when the three bleedings from the same rabbit were compared. For example, the initial serum sample (fourth week) from rabbit *F* produced three lines; however, serum from

the latter two bleedings (seventh and tenth weeks) produced a single line. Conversely, the initial serum sample from rabbit *A* produced only one line whereas three lines formed with serum from the latter two bleedings.

The possibility that the intense single lines produced by rabbit *F* antisera (seventh and tenth weeks) obscured the formation of additional weaker lines was examined by preparing two-fold dilutions of the antisera (to 1:16) and reacting them against the venom. Single lines were also obtained with diluted antisera. The lines, however, were more diffuse and not as intense as reactions with undiluted antisera.

The development of additional precipitin lines in reactions with sera from the latter stages of immunization may indicate that the rabbits are responding to antigens present in the venom in small amounts; to components that are poor antigens; or to the presence of antibodies synthesized during later stages of the immune response. On the other hand, several rabbit sera taken during the

Fig. 3. Gel-diffusion reactions of individual rabbit antisera A-F (outside wells) and Eastern coral snake venom (V), 100  $\mu$ g/ml. (centre well). a, Sera taken 4 weeks after start of immunization; b, 7 weeks; c, 10 weeks.

Table 1. NUMBER OF PRECIPITIN LINES PRODUCED BY EACH RABBIT ANTISERUM AT THREE STAGES OF IMMUNIZATION

Rabbit antiserum	Week of immunization		
	4th	7th	10th
A	1	3	3
B	2	1	2
C	2	4	3
D	3	2	2
E	3	2	2
F	3	1	1

precipitin lines than did sera from the fourth week. The work of Richter *et al.*<sup>8</sup> may provide an explanation for this observation. They found that antibodies in rabbit antisera tested during early stages of immunization (4 weeks) could precipitate with serum antigens and agglutinate sensitized red cells, whereas those present in late antisera (12–17 weeks) exhibited only the latter property. Some of our rabbit antisera may have had, qualitatively, relatively small amounts of precipitating antibody in the later bleedings which resulted in fewer precipitin lines.

A comparison of our data with those of Kochwa *et al.*<sup>5</sup> suggests that the neurotoxins in venoms of different snakes may have different antigenic properties, particularly in their capacity to elicit neutralizing antibodies. In their experiments both horse and rabbit antisera failed to protect mice against the neurotoxic effects of viper venom. When rabbits initially immunized with whole venom were subsequently immunized with only the neurotoxic fractions, however (a superimposed immunization), full protection by the antiserum against the effects of the venom was obtained. We used only whole coral snake venom but achieved complete protection against the neurotoxic effects of the venom.

Besides possible differences in the antigenicity of neurotoxins in different venoms, the production of neutralizing antibodies may depend on the route of injection of the venom. Staab *et al.*<sup>9</sup> showed that normal rabbits are very resistant to venom given intradermally and intraperitoneally. They suggested that this resistance, in the case of intraperitoneal injection, may be caused by an active detoxifying process. Kochwa *et al.*<sup>5</sup> used both the intravenous and intraperitoneal routes in their immunizations. Their use of the latter route may partially explain the lack of antibodies against neurotoxins in rabbit antiserum produced against whole viper venom. We used the subcutaneous route to immunize rabbits, and antiserum produced in this manner protected mice against the neurotoxic effects of the venom.

## Novel Alterations in Sera from Pseudopregnant and Deciduoma-bearing Rats

CONSIDERABLE attention has recently been focused on a new serum component of rats which was described by Darcy as being associated with rapid growth of tissue. Although it was not found originally in electrophoretically partitioned sera of healthy adult males or non-pregnant females, the protein was found in sera of foetal, neonatal, tumour-bearing, liver-regenerating, lactating, and pregnant rats<sup>1–5</sup>. Identified as an alpha-1-glycoprotein, it has been shown to be synthesized by the liver during the acute phase of an inflammatory response<sup>6</sup>. An apparently

mentally poisoned by cadmium and other metals<sup>7</sup> and in rats given single doses of *Escherichia coli* endotoxin<sup>8</sup>. A new protein migrating in the region of the alpha globulins has also been described in mice treated with a variety of toxic agents<sup>9</sup>.

Because there is rapid growth of tissue during the development of deciduoma in the uterus of the pseudopregnant rat (the uterine horns increase eight- to ten-fold in weight within four days), it was of interest to see whether the Darcy component was present in sera of decidua-bearing female rats. Because deciduoma formation is initiated by stimulating the uteri of pregnant or pseudopregnant animals (pseudopregnancy can be induced by various stimuli which cause an alteration of the normal 4-day oestrous cycle, a development of functional corpora lutea and an appearance of leucocytes in vaginal smears; this condition of pseudopregnancy persists for 11–14 days before oestrus is again experienced<sup>10,11</sup>), the sera of pseudopregnant animals were also examined and these compared with the sera of newborn and pregnant rats. The present communication is concerned with the novel alterations observed among electrophoretically separated components of sera from pseudopregnant, deciduoma-bearing rats.

Pseudopregnancy was induced by electrical stimulation applied to the cervix of the female rat on the day of oestrus (as determined by microscopic examination of daily vaginal scrapings) and on the following day<sup>11</sup>. Blood samples were taken from animals (*B.I.* strain, colony-bred albino rats originally of Wistar stock maintained in this department) before and at various intervals during pseudopregnancy but most often at 2, 8 and 10 days after the second electrical stimulation, (designated as leucocytic days of pseudopregnancy  $L_2$ ,  $L_8$  and  $L_{10}$ ).

Pre- and post-treatment sera from each animal were placed in adjoining troughs of starch-gels and electrophoresis was conducted at room temperature by the vertical technique of Smithies<sup>12</sup>; staining was with amido-black.

Fig. 1. Starch-gel electrophoretic separation patterns of two serum samples from each of three rats are presented showing, in particular, the slow alpha globulin zone. A new serum component, at site 6, may be seen in the sera of two of the rats, 196 above and 192 below, taken late in pseudopregnancy. The new serum component present on the eighth day but not the second day of pseudopregnancy was not seen in the sera of newborn or pregnant rats (compare pregnant rat 182, centre).

Sera from rats in late pseudopregnancy ( $L_8$  and  $L_{10}$ ) differed markedly from those taken before and in early pseudopregnancy ( $L_2$ ). A new component (position 6, Fig. 1, animals 196 and 192) was seen in four of thirteen sera obtained on  $L_8$  but not in any of those taken on  $L_2$  of pseudopregnancy. In addition, smaller amounts of components 1, 2 and 3 were present in sera on  $L_8$  than were seen in those on  $L_2$ . Sera taken before electrical stimulation of these animals appeared much the same as sera taken on  $L_2$  of pseudopregnancy (for example, see the pre-bleedings of the five rats in Figs. 2 and 3).

Attempts were made to see whether component 6 also existed in pregnant or neonatal rats. None of the sera from eleven pregnant rats appeared to have component 6 despite the fact that they were taken at various times during pregnancy (for example, see animal 182, Fig. 1), nor was component 6 present in sera of neonates (eight in two pools of four). The alpha-1-glycoprotein described as present in pregnant and neonatal rats, however, was not seen in the sera of rats from this colony. As an added precaution, sera from all neonates and from four of the pregnant animals were derived from decapitated animals as was described by Beaton *et al.*<sup>2</sup> and not according to our usual procedure, that is, not from heart blood taken from etherized animals.

Fig. 2. Electrophoretic patterns are shown of serum samples taken before and after initiation of decidual formation. In sera taken four days after start of decidual formation, the slow alpha globulin (component 4 of animals 43 and 125) is seen decreased, while components 2 and 3 are markedly increased. These changes are barely visible, if at all, in sera of a third animal (199) that formed a small decidualoma.

Fig. 3. Serum changes are shown in two rats experiencing formation and regression of decidualoma. The increases in components 2 and 3, apparent in sera taken four days after initiation of decidualoma, are no longer visible on the thirteenth day. By the thirteenth day, when the serum patterns have returned to normal, the decidualoma have also regressed causing uteri to look normal.

To examine sera of animals possessing decidualoma, pre-bled adult females which weighed 140–210 g were made pseudopregnant by electrical stimulation of the cervix. On  $L_4$  of pseudopregnancy, as judged from the persistence of leucocytic-type vaginal smears, laparotomy was performed under ether anaesthesia and both horns of the uterus were stimulated to produce decidualoma by intraluminal scratch. This trauma serves to initiate decidualoma formation in the sensitized pseudopregnant rat<sup>10,11,13</sup>. Four days later ( $L_8$ ), the animals were re-bled and either autopsied to confirm the presence of decidualoma

or their uteri were examined by laparotomy. These rats were then sutured and re-bled on  $L_{17}$  when decidual regression had occurred. Thus, small samples of serum taken before, during, and following development of decidualoma were available for investigation.

Electrophoretic separation of sera from sixteen animals bearing decidualoma of various sizes showed ten with a regular alteration which involved more than one component in the slow alpha globulin zone. Typically, the slow alpha globulin was seen to be a narrower less intensely staining band in sera taken four days after start of decidualoma formation ( $L_8$ ) than in sera taken 5 days before decidualoma initiation (Fig. 2, component 4 of animals 43 and 125). At the same time, there was a marked increase in components 2 and 3.

A direct correlation was observed between the degree of the decidual response and the degree of change in serum components. When decidual responses were small, the serum changes were not dramatic (Fig. 2, rat 199). The sera from four control rats the uteri of which had been traumatized along with experimental animals showed no visible changes; these animals were not pseudopregnant and thus were incapable of developing decidualoma.

To ascertain the duration of these changes in the sera of decidualoma-bearing animals, sera taken on  $L_{17}$ , 13 days after initiation of decidualoma, were examined. At this time uteri generally return to normal and animals experience oestrus once more. As may be seen from Fig. 3, the serum components also reverted to their former patterns, that is, after first showing an increase in concentration, components 2 and 3 were seen to be diminished once more while component 4 was first decreased and then later replenished or even slightly augmented.

Whether formation of decidualoma triggers an increased production of serum components 2 and 3 at the expense of a slow alpha globulin (component 4) or simply blocks utilization or catabolism of 2 and 3, while hastening circulatory removal of component 4, remains undetermined. Reversion of each of the three components to normal concentration after decidual regression points to an apparent interdependence among these serum components.

The source of components 2 and 3 is also unknown. Because they are normally present in sera, but in small amounts when decidual tissue is not present, it may be possible that pre-decidual cells in the uterus produce a small amount of each component under ordinary circumstances but much more as the cells develop into the decidual. Alternatively, components 2 and 3 may be manufactured in the liver in support of tissue growth.

A comparison on the same starch-gel of component 6, seen here in pseudopregnant females, with the alpha-1-glycoprotein of Darcy could not be made because neither of these components was present in sera from pregnant or neonatal animals of this colony. A comparison of photographs of the two components, however (that is, Fig. 1 here with Fig. 1 in refs. 2, 4 and 7), reveals them to be in distinctly separate positions and therefore not identical.

A further difference between the two serum components may be the manner in which they arise; whereas the alpha-1-glycoprotein is thought not to appear at the expense of other serum components<sup>4</sup>, the appearance of component 6 coincides with a diminution in concentration of components 1, 2 and 3. The interrelationship that apparently exists among components 1–6 suggests they may be members of a common family of alpha globulins.

That only one-fourth of the pseudopregnant animals and two-thirds of the decidual animals were capable of expressing the serum differences may be referable to genetic differences. Perhaps genetic differences will also explain the inability of pregnant and neonatal rats of this colony to produce the reproduction associated protein.

Quantitative aspects of the changes in sera would be essential to affirm the visual evidence reported here for rats with decidualoma and those experiencing pseudopregnancy.

### Recognition of Altered Autologous Constituents as Foreign by Phagocytic Cells

THE passage of antigen into an organism and its subsequent uptake by specialized cells are essential preliminary events in any process in the synthesis of antibody.

It has been shown that these "specialized" cells (for example, circulating leucocytes and macrophages of the reticulo-endothelial system) engulf particulate antigens (for example, from microbes, protozoa and red blood and other cells) by means of phagocytosis<sup>1,2</sup>. They will also take up isolated protein macromolecules<sup>3-7</sup> or complex bacterial endotoxins (both thermostable and thermolabile) and some exotoxins by means of pinocytosis<sup>7,8</sup>.

These well known mechanisms may or may not be necessary antecedents of activation of the antibody production system. Moreover, it is not known whether any degree of recognition of self is possessed by the phagocytic cell series. In order to explore this point, we have investigated the rates of pinocytosis and phagocytosis of autologous proteins (for example, gamma-globulins) and cells (for example, red cells) using both untreated cells and cells structurally modified by means of physical or chemical treatment.

Pinocytosis of gamma-globulins was investigated by observing under a fluorescent microscope a mixture which had been incubated at 37° C for 30 min and which consisted of 4.5 ml. of a suspension of leucocytes taken from guinea-pig peritoneal exudate (90,000 cells/mm<sup>3</sup>) in Alsever solution and 0.5 ml. of a 1 per cent suspension of fluorescent autologous gamma-globulins in saline. The exudate was produced in guinea-pigs by means of two successive daily intraperitoneal injections, each with 30 ml. of 5 per cent polyvinylpyrrolidone at pH 7. Ninety per cent of the phagocytic cells obtained in this way were polymorphonuclear leucocytes, while the other 10 per cent were monocytes. Autologous gamma-globulins were isolated by chromatography on 'Sephadex' DEAE and later conjugated with fluorescein isothiocyanate<sup>9</sup>. Before conjugation, each sample was divided in two equal parts, one of which (the control) was not treated; the other portion was heated for 10 min at 80° C (Fig. 1).

Results are given in Table 1 as the percentage of phagocytes showing pinocytosis (five hundred elements were counted in each sample) and quantitative data of this phenomenon are expressed in terms of the number of pinocytic vacuoles per leucocyte.

Phagocytosis of red cells was investigated in a similar way, but light microscopy was used after staining with May-Grünwald-Giemsa. The exudate was produced in

Table 1. PINOCYTOSIS OF AUTOLOGOUS GAMMA-GLOBULINS

	Mean rate of pinocytosis (per cent)	No. of pinocytic vacuoles/leucocyte
(A) Controls (non-treated gamma-globulins)	13.7 ± 1.87	10.09 ± 0.6
(B) Altered gamma-globulins	65.87 ± 2.8	10.04 ± 0.73

The difference between (A) and (B) is highly significant.

guinea-pigs by means of two intraperitoneal injections: the first consisted of 10 ml. of 5 per cent glycogen in Ringer solution, and the second (48 h later) of 30 ml. of 5 per cent polyvinylpyrrolidone.

Autologous red cells obtained by cardiac puncture were washed three times and finally resuspended in saline (1.4 × 10<sup>6</sup> cells/mm<sup>3</sup>). Each sample was later divided into four equal parts each of 0.5 ml. The parts were treated as follows: (1) one part (the control) was maintained as such; (2) another part was incubated at 37° C for 30 min with an equal amount of 1 per cent periodic acid; (3) another was incubated at 37° C for 90 min with an equal amount of cathepsin solution (that is, 10 mg cathepsin NBC/ml., pH 5 acetate veronal buffer, containing 0.025 molar cysteine hydrochloric acid); the final part was incubated at 37° C for 90 min with an equal amount of a solution containing 0.5 mg *Clostridium perfringens* lecithinase/ml.).

Each sub-sample of the suspension of red blood cells was later mixed in a silicon-coated tube with the corresponding leucocyte suspension (the numerical ratio of red cells to leucocytes was 15:1 in each mixture) and immediately incubated at 37° C for 90 min. Results are given in Table 2, in terms of the percentage of leucocytes showing phagocytosis (in every mixture 500 elements were counted), and quantitative data are expressed in terms of the number of erythrocytes phagocytosed by one cell. In some instances, the leucocytes were washed in order to exclude the action of any "specific opsonization" as a result of serum components (Table 2, D').

Table 2. PHAGOCYTOSIS OF AUTOLOGOUS RED CELLS

	Mean rate of phagocytosis (per cent)	No. of erythrocytes phagocytosed/leucocyte
(A) Controls (non-treated cells)	0.3 ± 0.1	one erythrocyte/leucocyte
(B) Cells following treatment with cathepsin	0.93 ± 0.2	one erythrocyte/leucocyte
(C) Cells following treatment with periodic acid	21.46 ± 8.45	one erythrocyte/leucocyte
(D') Cells following treatment with lecithinase	22.1 ± 1.61	one erythrocyte/98 per cent of the leucocytes, and two erythrocytes/2 per cent of the leucocytes
(D'') As D' but with washed leucocytes	20.26 ± 1.56	

Supplementary control in order to eliminate any possible specific opsonization due to serum components.

Differences between (A) and (B), (A) and (C) and between (A) and (D') are highly significant. The difference between (D') and (D'') is not statistically significant.

The results clearly show that:

(1) The rate of uptake of autologous unaltered red cells is negligible (0.2 per cent, see Table 2). Previously, we

Fig. 1. Pinocytosis of thermally altered autologous gamma-globulins. (Fluorescent microscopy, × 1,250.)

have not been able to determine whether pinocytosis of autologous non-treated gamma-globulins (observed in 15 per cent of the leucocytes counted, Table 1) results from some "artefactual" alteration of gamma-globulins, during manipulation for reparation and conjugation, or can be attributed to some minimal basic rate of physiological pinocytosis. The former seems to be the most likely cause.

(2) Certain artificially induced structural alterations of autologous components (either macromolecules or cells) occur, which result in an increase of their pinocytic or phagocytic rates.

(3) At the phagocytic level, discrimination between autologous and non-autologous material occurs independently from humoral specific factors, even in chordates. When leucocytes were washed the differences between the phagocytic rates of altered and unaltered red cells (Table 2, D") and pinocytosis of altered and unaltered gamma-globulins were not diminished. These data are in agreement with the observations showing that opsonins are not necessarily involved in the process of phagocytosis of aged or damaged erythrocytes, by leucocytes<sup>10</sup>.

(4) Not all the components of a cell are equally relevant in the recognition process at the phagocytic level, but the superficial ones tend to be prominently displayed. (a) Cathepsin, which affects haemoglobin (see Table 2, B), increases only slightly (however, statistically significantly) the rate of erythrophagocytosis. This is probably because haemoglobin is "hidden" within the cell and virtually unable to interact with the phagocytic cell wall during the very moment of realization of phagocytosis (that is, haemoglobin structure is scarcely recognizable in the erythrophagocytosis process). (b) Lecithinase, which results in hydrolysis of lecithin—a component of the membrane of red cells (and, as such, "displayed" for interaction with the phagocytic cell membrane)—greatly increases the rate of erythrophagocytosis (Fig. 2). (c) Periodic acid, which affects the hydroxy groups of carbohydrate components and the alpha-amino alcohol functions of proteins in the cell wall of red blood cells<sup>11-13</sup>, also considerably increases the rate of phagocytosis (Fig. 3).

This interpretation is in close agreement with the now unanimously accepted idea that the recognition of "foreign" red cells as antigens is a consequence of the ability of the immunological defence mechanism of chordates to discriminate even fine natural differences of structure (when displayed for interaction) between functionally similar macromolecules of cells. The gradual increase of phagocytosis, paralleling the phylogenetic distance between the "donor" and the "host" species<sup>12</sup>, seems, in fact, to mirror the more easy recognition of

Fig. 2. Phagocytosis of autologous red cells following treatment with lecithinase. May-Grünwald-Giemsa staining ( $\times 1,250$ ).

Fig. 3. Phagocytosis of autologous red cells following treatment with periodic acid. May-Grünwald-Giemsa staining ( $\times 1,250$ ).

larger structural differences in physiological conditions. From the point of view of "immunological recognition", "natural" (that is, genetically controlled) and "artificially induced" differences in structure between macromolecules or cells are both recognizable to the same degree, provided that they are "adequately displayed" for interaction with the recognition mechanism of the corresponding defence level. At the level of the phagocytic defence mechanism, "adequately displayed" means situated on the surface (that is, on the membrane or cell wall).

The ability to discriminate such differences is an attribute of leucocytes and macrophages, at the same time and before discrimination by antibody synthesizing lymph-plasmacyte clones<sup>14,15</sup>.

We thank Sir Macfarlane Burnet for his encouragement in this work and Professor G. J. V. Nossal for suggestions and for help in preparing the manuscript. We also thank Mrs. Giorgina Dimitrescu for technical assistance.

### Solid Phase Radioimmunoassay

ALL forms of radioimmunoassay used at present include a procedure to separate free and bound tracer antigen when equilibrium is reached in the incubation mixture. This separation may involve precipitation by a second antibody<sup>1,2</sup>, electrophoresis<sup>3,4</sup>, chromatoelectrophoresis<sup>5</sup>, ion exchange<sup>6</sup>, solvent fractionation<sup>7</sup>, gel filtration<sup>8,9</sup>, salt precipitation<sup>10</sup>, or adsorption to charcoal<sup>11</sup>. The need to

use such formal isolation procedures increases the length and complexity of the assay and introduces a number of possible sources of error.

For these reasons we felt that a system in which both the antigen-antibody reaction and the separation of bound and free tracer antigen could be achieved in a single step would be a valuable innovation. The application of substituted polymers conjugated to the antigen for the isolation of antibody<sup>12,13</sup> suggested the possibility of using this type of procedure in reverse to achieve this aim. In the presence of antibody coupled to an insoluble polymer, antigen which becomes bound to antibody will be attached simultaneously to a solid supporting medium. Then, if radioactive tracer antigen is present in the system, the solid phase has simply to be washed and counted to quantitate the degree of antibody binding. This would result not only in a simple and rapid radioimmunoassay, but also in the elimination of a variable number of handling and other errors which are inherent in the separation techniques mentioned.

The feasibility of this method was tested with a solid phase antibody consisting of diazo-polystyrene coupled to rabbit antiserum to human growth hormone, and human growth hormone labelled with iodine-131 as tracer antigen. This initial experiment showed that the binding of labelled human growth hormone to the solid phase was reduced by the presence of unlabelled human growth hormone over the range 1–10  $\mu\text{g}$ .

This demonstration of the suitability of the solid phase antibody as the basis of a radioimmunoassay led us to extend the sensitivity of the method to the physiological range. This aim was facilitated by the use of a solid phase support consisting of the isothiocyanate derivative of a graft copolymer of poly(tetrafluoroethylene) ('Fluon G4') and styrene. This copolymer<sup>14</sup>, which was developed for use in analytical, synthetic and immunochemical procedures, allows a variety of reactive substituents to be attached to the aromatic rings on the surface of a dense and inert core of poly(tetrafluoroethylene).

An example of the use of this polymer, coupled to anti-human growth hormone rabbit gamma globulin, for the radioimmunoassay of human growth hormone, is shown in Fig. 1. In this experiment, 5 mg of solid phase-antibody was incubated for 12 h with 0.2  $\mu\text{g}$  of labelled human

Fig. 1. The effect of adding 5–200  $\mu\text{g}$  of human growth hormone (HGH) on the binding of tracer amounts of human growth hormone labelled with iodine-131 by solid phase-antibody.

Fig. 2. The effect of adding 0.2–20  $\mu\text{g}$  human growth hormone (HGH) on the binding of tracer amounts of human growth hormone labelled with iodine-131 to solid phase-antibody. The concentration of antibody in this solid phase preparation was approximately a tenth of that used to achieve the result shown in Fig. 1.

growth hormone in the presence of increasing quantities of unlabelled human growth hormone. The binding of tracer human growth hormone to the solid phase was sharply reduced by the addition of as little as 10  $\mu\text{g}$  of unlabelled growth hormone. The use of a solid phase more lightly coated with antiserum, and an incubation period of 2 days, enabled 0.2  $\mu\text{g}$  of human growth hormone to be detected giving a standard curve over the range 0–20.0  $\mu\text{g}$  (Fig. 2). The application of this method to the estimation of antigen in the subnanogram range should be readily achieved by further reduction in the amount of antibody present in the system, with corresponding increase in the period of incubation and the specific activity of the tracer antigen.

The use of solid phase systems in protein chemistry has been largely confined to the field of peptide synthesis, as extensively developed by Merrifield<sup>15</sup>. The present communication reports a further application of solid phase for the micro-estimation of antigen. Its use in the technique of radioimmunoassay is a new concept<sup>16</sup> which confers several advantages over the methods which are at present in use. These advantages derive from the ability of the solid phase-antibody system to remove tracer antigen from solution at the same time as it is bound by specific antibody.

We have found that the addition of vast quantities of unlabelled human growth hormone to solid phase-antibody which has been allowed to bind labelled human growth hormone does not result in displacement of the tracer. Thus, the binding of this antigen to the solid phase-antibody appears to be an irreversible process. The consequences of this irreversible binding are of great importance, because they lead to three further effects which are of value in the procedure of radioimmunoassay. First, the speed of the antigen-antibody reaction is enhanced by the removal of the product of reaction. Second, the technique of disequilibrium is particularly applicable to this system, because the unlabelled antigen can be removed by washing the solid phase before adding the tracer. This allows a considerable improvement in sensitivity by avoiding dilution of the added tracer by the unbound antigen which would otherwise remain in the system.

Finally, the ability to wash the solid phase-antibody after reaction with an unknown antigen in serum allows

removal of serum proteins before the addition of tracer. This will avoid the "damage" which constantly occurs when tracer quantities of labelled protein hormones are incubated in the presence of serum.

We suggest that the combination of these several advantages of the solid phase-antibody system should make it a powerful tool for measuring minute quantities of antigen by a radioimmunoassay procedure.

## MICROBIOLOGY

### Changes in Transforming DNA in *Pneumococcus*

DURING the course of an investigation involving the transforming ability of pneumococcal DNA, an interesting correlation was found between the transforming activity of lysates prepared at varying times from the same culture and the number of viable organisms in the culture. *Streptococcus pneumoniae*, strain Aml, an aminopterin resistant strain derived from strain R36A of Avery *et al.*<sup>1</sup>, was grown first in P medium and then in NS medium in the manner designed to promote competence<sup>2</sup>. At appropriate times, 1.0 ml. aliquots of the culture in NS medium were lysed in the presence of sodium citrate by the addition of sodium deoxycholate, and the DNA was precipitated with ethyl alcohol using sodium hyaluronate as coprecipitant<sup>3</sup>. In one of the experiments to be discussed another aliquot was taken at the same time as that for the lysate, and, after suitable dilution, was plated out in triplicate for a viable count. The lysates were assayed for their transforming activity with respect to resistance to aminopterin by a conventional method<sup>2</sup>, using *Str. pneumoniae* strain Cl. 3 as the receptor organism.

The results obtained are summarized in Table 1. The viable counts have been expressed as multiples of the count obtained at the time of the first sample. In the first experiment the culture did not undergo a complete division during the period of observation. The viable counts were not corrected for the average chain length, but the chain length would not be expected to increase by more than 1 per cent in this time. In the second experiment the viable count was not carried out and the figures for the multiple of the viable count quoted in Table 1 are the average from three growth curves determined in comparable conditions in the course of other experiments.

Table 1. TRANSFORMING ACTIVITY OF LYSATES PREPARED AT DIFFERENT TIMES FROM THE SAME CULTURE

Time at which lysate was prepared (min)	No. of transformants (T) ( $\times 10^3$ )	Viable count ( $\times 10^6$ )	Multiple of viable count (M)	Estimated multiple of viable count (see text)	T/M $\times 10^3$
Experiment 1					
100	3.87	8.63	1	—	3.87
105	8.38	9.70	1.13	—	7.34
110	10.2	11.2	1.3	—	7.8
115	9.30	9.77	1.13	—	8.2
Experiment 2					
80	0.9	—	—	1	0.9
100	4.3	—	—	1.51	2.85
120	42.4	—	—	1.87	22.67

The numbers of samples are small for an extensive statistical analysis, but it will suffice to comment that the results of experiment 2 show no overlap, while in experiment 1 the transforming activity at 110 min compared with that at 100 min was significant at  $P < 0.05$  in the Student *t* test.

The ratio of the number of transformants to the multiple of the viable count shows a marked increase with the increase in age of the culture from which the transforming lysate is prepared. If it is assumed that the relative number of organisms present at each time can be taken as a rough measure of the relative amount of the *AmiA-r1* gene contained in each lysate, it would appear that the increase in the transforming activity of the lysates cannot be explained solely by an increase in the amount of the gene in each aliquot. This would suggest that qualitative changes occur in the DNA during its replication which manifest themselves as changes in its transforming ability. The lysate would also contain DNA contributed from any autolysed cells, but, at the very most, this would represent only a doubling, and the DNA itself would have been exposed to DNase simultaneously released.

An alternative explanation would relate the increased transforming activity to an increase in the amount of the gene in each cell as a result of DNA synthesis disproportionate to the extent of cell division. This would imply, to account for the highest ratio observed, that gene replication of seven-fold or more occurred before cell division, and this explanation seems less likely. Further work is in progress to try to elucidate the phenomenon.

### Controlled Investigations in Baboons (*Papio cynocephalus*) on Transmission of SV-5 Virus by Contact

THE intranasal infection of vervet monkeys (*Cercopithecus aethiops*) with SV-5 virus, which belongs to the para-influenza 2 group<sup>1</sup>, has been reported to result in a disease pattern usually observed in naturally occurring parainfluenza virus infections of man<sup>2,3</sup>. It was suggested, therefore, that this experimental model was potentially useful for the evaluation of appropriate antiviral drugs and also for investigation of the pathology and pathogenesis of acute respiratory viral disease.

Observations made in this laboratory suggest that baboons (*P. cynocephalus*) can also be intranasally infected with SV-5 virus, and, furthermore, that this virus infection can be transmitted to uninfected monkeys by contact. The contact infection was thought to be of interest because

it could be useful as a prophylactic antiviral test system. This communication summarizes the results of controlled experiments which have been conducted to compare the pattern of SV-5 infection in baboons inoculated intranasally and in their cage-mates.

Altogether, fifty-one young baboons, ranging in weight from 3 kg to 4 kg and free from signs of acute respiratory disease, were used in this work. The animals were accommodated in suitable cages, the majority in pairs and some three to a cage, in an air-conditioned animal isolation building. After preinoculation blood samples and combined nasopharyngeal swabs had been taken from each baboon, one animal in each cage was inoculated intranasally with 2 ml. of tissue culture fluid containing  $10^{6.7}$  TCID<sub>50</sub>/ml. of SV-5 virus. The baboons thus inoculated were then referred to as "inoculated" and their cage-mates as "contact". Combined nasopharyngeal swabs were then taken from all baboons at varying times, between 1 and 30 days after infection, and also on day 40. Serum specimens were taken on days 20 and 40. Each swab was tested for the presence of virus and each serum specimen for HI (haemagglutination inhibiting) antibody as previously described<sup>3</sup>. The varied amounts of fluid absorbed by each nasopharyngeal swab made it impossible to titrate virus, and therefore the virus isolation results were recorded as positive or negative. The results of virus isolations are summarized in Table 1 and Fig. 1, and the antibody response is shown in Fig. 2.

Table 1

Experimental group	Beginning of virus excretion (range in days)	Duration of virus excretion, Virus positive/group total during indicated periods (days)				Total virus positive/group total
		8-14	15-21	40	Group mean	
Inoculated	1	16/25	8/25	1/25	14.6	25/25
Contact	5-21	23/26	2/26	0/26	11.4	25/26

Table 1 shows that although the inoculated baboons were all virus positive 24 h after inoculation, the contact baboons began to excrete virus considerably later, that is between day 5 and day 21. There was also some difference between these two groups in the duration of virus excretion. While the great majority of contact baboons (twenty-three out of twenty-six) excreted virus for 8-14 days, the inoculated baboons excreted virus for longer periods. Table 1 also shows that one contact baboon remained virus negative throughout the whole observation period. This animal had a low titre (1.7) of antibody activity in its serum before exposure to virus, and there was a four-fold rise to a titre of 1:28 on day 40.

Fig. 1. Frequency distribution of time periods between exposure of inoculated baboons to virus and its appearance in the nasopharynx of contact baboons.

Fig. 2. Mean values of the HI antibody response of baboons to infection with SV-5 virus. —, Inoculated; ---, contact.

Fig. 1 shows frequency distribution of time periods between exposure to virus and its appearance in the nasopharynx of contact baboons. The frequency distribution resembles the normal curve with a slight skewness rising more abruptly on the short side and tailing off on the long side. The range of these periods is an important epidemiological characteristic because it determines the time interval necessary for virus transmission from SV-5 infected monkeys to their cage-mates.

As in our previous experiments<sup>3</sup>, mild clinical signs of infection were present in both groups of animals, but they were difficult to measure accurately. There were neither complications nor sequelae. The HI antibody response in both groups of experimental baboons is summarized in Fig. 2, from which it is clear that the animals developed an antibody response. In view of the prolonged virus excretion in the nasopharynx and the apparent lack of a viraemic state<sup>3</sup>, it was not surprising that the antibody response was weak.

To conclude, the contact infection of baboons with SV-5 virus seems to be a practicable model system, potentially useful for pre-clinical evaluation of antiviral drugs against viral infections of the upper respiratory tract and also for investigation of important epidemiological characteristics of these infections.

We thank Mr. T. B. Pendry for technical assistance.

### *Mycoplasma hominis* in Ayre's Smears

ORGANISMS of the genus *Mycoplasma* are frequent inhabitants of the female genital tract. A common species is *Mycoplasma hominis* type I, and this organism has been isolated from about 20 per cent of normal women<sup>1</sup>.

Unlike bacteria, *Mycoplasma* have no rigid cell wall and are difficult to detect in heat fixed smears. The morphology can be preserved when less traumatic methods of fixation are used, and it occurred to us that it might be possible, if enough of the organisms were present, to see mycoplasmas in cytological smears fixed in alcohol. Preliminary studies showed that when a heavy growth of mycoplasmas had been obtained from a vaginal swab, the Ayre's smear frequently had a "dirty" appearance. Ayre's smears and vaginal swabs were subsequently examined from 233 ante-natal patients. The vaginal swabs were plated on to blood agar and on to pleuropneumonia-like organism (PPLO)-agar and examined after 72 h incubation. *Mycoplasma* sp. were grown from sixty-five swabs (24 per cent); the growth was graded according to the number of colonies established and all strains grown were identified as *Mycoplasma hominis* type I by the growth inhibition test<sup>2</sup>. The Ayre's smears were stained by Papanicolaou's method. The cultural results were not known to the microscopist at the time when the Ayre's smears were examined. The combined results are shown in Table 1.

Growth of <i>M. hominis</i>		Morphological presence in Ayre's smear
Heavy	25	22 (88 per cent)
Moderate	11	6 (54 per cent)
Scanty	19	3 (16 per cent)
Negative	178	5 (3 per cent)

Where there was cultural evidence of a heavy infection of the cervix with mycoplasma, the sample obtained by the Ayre's smear technique showed, under low power, a characteristic "dirty" appearance (Fig. 1). There were innumerable moderately haematoxyphil minute micro-organisms festooning the squames and often forming bluish chains between the cells. Under the 4 mm and 2 mm objectives the organisms were mainly coccoid, the cell outline being less distinct than with bacteria. Where the organisms lay thickly they stained a purplish blue; they did not spread evenly over the glass slide as bacteria often do. Table 1 shows that there was a close correlation between the proportion of morphologically positive Ayre's smears and the heaviness of growth; where the growth was scanty, recognition of the organisms in the film was less reliable. This is regarded as evidence that the micro-organisms seen were mycoplasmas.

A "dirty" appearance in Ayre's films due to exudate, debris, cytolysis and clumps of bacteria is mentioned by Koss and Durfee<sup>3</sup> as characteristic of infection of the cervix or vagina; similarly, a "dirty" appearance in Ayre's films from cases of amoebiasis of the genital tract has been described<sup>4</sup>. Although bacteria such as lactobacilli and coliforms also appear haematoxyphilic in an Ayre's smear, and when numerous may also contribute

Fig. 1. Ayre's smear. Large numbers of the typically coccoid organisms seen in between and overlying the vaginal squames. Papanicolaou stain ( $\times 320$ ).

Fig. 2. Ayre's smear. Mingled with the vaginal squames and polymorphs are numerous lactobacilli. Papanicolaou stain ( $\times 400$ ).

Fig. 3. Ayre's smear. Numerous small cocco-bacilli. Papanicolaou stain ( $\times 400$ ).

a "dirty" appearance, these can readily be distinguished (Fig. 2). Smaller organisms such as *Haemophilus vaginalis* were distinguished from the essentially coccoid *Mycoplasma* by their rod-like shape when examined under the 2 mm objective (Fig. 3).

The culture media used were unsuitable for isolating the *T*-strains of mycoplasma, which are also common inhabitants of the genital tract<sup>5</sup>. This may account for five slides which were classified as morphologically positive when there was no growth of mycoplasma.

Infection of tissue cultures by *Mycoplasma* affects the rate of cell growth and produces chromosome changes<sup>6</sup>. Chromosome abnormalities can be demonstrated in cells taken from dysplastic or early pre-invasive cervical epithelium<sup>7</sup>. Our results show that a heavy *Mycoplasma* infection of the genital tract can be diagnosed with fair accuracy from an Ayre's smear, and it would be possible to use this method in a retrospective study to ascertain whether the morphological presence of *Mycoplasma* in the films can be correlated with the nuclear changes associated with cervical dysplasia or *in situ* carcinoma.

### Synergistic Fungistatic Effect of Tetrazolium-Saliva Mixtures

THE presence of an antifungal factor has been reported in normal human serum and in the conjunctival mucosa<sup>1-3</sup>. This work was initiated to determine whether saliva possesses an identical or similar substance. Stimulated whole saliva, parotid and sub-maxillary secretions were collected from ten apparently normal individuals and tested by placing aliquots in cylinders on Pagano-Levin agar, lawn seeded with *Candida albicans*, *Candida tropicalis* and *Saccharomyces cerevisiae*. No zones of inhibition were observed. Serum constituents (globulins) excreted in saliva are approximately one tenth of their concentration in serum and so it was decided to concentrate the salivary specimens to dryness by lyophilization. The solid constituents were then resuspended in sterile distilled water to give final concentrations 2.5-20 times greater than in saliva. Such concentrations manifested antifungal properties when tested as previously described. No inhibitory activity was discernible when Sabouraud's glucose agar, blood brain heart infusion agar or brain heart infusion agar were used, and so it seemed that the constituent in the Pagano-Levin medium which might be responsible for this activity was triphenyltetrazolium chloride, a redox indicator. The compound is reduced by *Candida tropicalis* to a red pigmented crystalline formazan whereas strains of *Candida albicans* usually fail to do so. At least five times the concentration of tetrazolium salt in Pagano-Levin medium is necessary for inhibition.

Lyophilized whole saliva or parotid or sub-maxillary secretions, concentrated twenty times, gave zones 25-30 mm in diameter, whereas specimens concentrated two and a half times produced zones of 12 mm diameter. Saliva from some individuals did not possess the antifungal factor and stringy mucinous salivas showed less activity than did non-viscid salivas. Individuals ill with upper respiratory infections showed little or no activity during the period of the acute symptoms of the disease.

The factor has been found to be filterable through glass fibre paper, 'Berkefeld', 'Selas' and 'Millipore' filters. Centrifuged specimens had fungistatic activity in the supernatant but not in the sediment. The factor is dialysable and can be concentrated by evaporation at 100° C. According to Louria and Brayton<sup>4</sup> sera of normal individuals contain a factor inhibitory to *Candida albicans* and *Candida stellatoidea* but not towards other *Candida* species, *Cryptococcus neoformans* or *Saccharomyces cerevisiae*. The factor these investigators have described was active after subjection to a temperature of 70° C for 1 h, dialysable, and had a molecular weight of approximately 15,000. Igel and Bolande<sup>5</sup> reported a serum factor which was non-dialysable and was inactivated at 70° C, but which was inhibitory towards the *Cryptococcus neoformans*. They also found a factor in saliva which inhibited *Cryptococcus neoformans*, but was distinct from the serum factor in that it was dialysable and the diffusate remained active after being subjected to 70° C for 2 h.

Our findings disagree with those of Louria and Brayton in that serum samples did not show inhibitory activity on our test medium, whereas saliva samples did. As suggested by the findings of Igel and Bolande, the factor in saliva is apparently distinct from that present in serum.

### Phosphorylation of Pyridoxine by *Escherichia coli* B

THE recent demonstration of a pyridoxine phosphate oxidase in extracts of *Escherichia coli*<sup>1,2</sup> and the accumulation of pyridoxine phosphate by a mutant of this organism blocked in this step<sup>3</sup> suggests that this oxidation is the ultimate step (A) in the biosynthesis of pyridoxal phosphate. If this is true, the kinase step (B) may be expected to have greater specificity for pyridoxine than for pyridoxal.

This communication reports the testing of this hypothesis.

Cell-free extracts of *E. coli* were prepared by ultrasonic disruption of 1 g of lyophilized cells in 25 ml. of 0.15 molar potassium phosphate at pH 7.0. The broken cells were centrifuged for 30 min at 2° C at 40,000g and the supernatant fluid was dialysed overnight against 4 l. of distilled water at 5° C. Pyridoxal phosphate was assayed by the apotryptophanase method<sup>4</sup>. Pyridoxine phosphate was first converted to pyridoxal phosphate by the rabbit liver oxidase method of Wada and Snell<sup>5</sup> and then assayed. Pyridoxine phosphate was used to standardize this reaction. The optimum concentration of magnesium sulphate for the kinase with either substrate was 10<sup>-4</sup> molar. Protein was measured by the method of Lowry *et al.*<sup>6</sup>. Both substrates were chromatographically pure.

Table 1 shows that *E. coli* extracts can phosphorylate pyridoxine at much lower concentrations than they can phosphorylate pyridoxal. This finding and the oxidase findings are evidence in support of the foregoing biosynthetic sequence for pyridoxal phosphate.

Table 1. ACTIVITIES OF PYRIDOXINE AND PYRIDOXAL AS SUBSTRATES FOR PHOSPHORYLATION\*

mμmoles of substrate	Duration of kinase reaction (min)	Duration of oxidase reaction (min)	mμmoles product formed
(1) None added	60	30	None detected
5, pyridoxine	60	30	1.5
15, pyridoxine	60	30	5.5
25, pyridoxine	60	30	6.0
40, pyridoxine	60	30	6.5

### Influence of Challenge Strain on Potency of Pertussis Vaccines in Mice

Eldering, Holwerda and Baker<sup>1</sup> have recently shown that, in mouse-protection tests with pertussis vaccines, the species-specific agglutinin (factor 1) is more important than the type-specific agglutinogens (factors 2 and 3). This confirms my own findings<sup>2</sup> and those of Andersen

Table 1. PASSIVE PROTECTION OF MICE, WITH FACTOR-1 ANTISERUM, AGAINST INTRACEREBRAL CHALLENGE WITH *Bordetella pertussis*\*

Challenge strain	Serum	No. of deaths/No. challenged				Total
		2	3	4	5	
353/Z	Normal	12/15	13/15	10/14	8/14	43/58
	Factor-1	1/15	1/14	4/15	2/14	8/58
W.18-323	Normal	12/15	12/15	15/15	10/14	49/59
	Factor-1	7/15	6/15	9/14	5/14	27/58

\* Data abstracted from previous publications<sup>4,5</sup>.

and Bentzon<sup>3</sup> with actively immunized mice, and emphasizes the limitation of the standard mouse-protection test in assessing the prophylactic potency of pertussis vaccines<sup>4</sup>. It is not, however, incompatible with the demonstration of type-specific immunity in mice by passive protection with mono-specific sera and subsequent challenge with selected strains of various different serological types<sup>4,5</sup>. It does not, moreover, disprove the importance of factors 2 and 3 in human prophylaxis against strains of *Bordetella pertussis* which occur naturally<sup>6-10</sup>.

Eldering *et al.*<sup>1</sup> were unable to explain one of their further observations—that vaccines, regardless of serotype, protected mice more readily against challenge with strain 353/Z (which possesses only factor 1) than against strain W.18-323 (which possesses factors 1, 2 and 3), although the two strains are of approximately equal mouse-virulence. They suggested that the matter might be explored further by passive protection experiments. Such experiments have already been performed in our laboratories<sup>4,5</sup>: antisera to factors 2 and 3 did not protect mice against either of these challenge-strains; antiserum to factor 1 protected against both strains, but it protected against 353/Z significantly better than against W.18-323. The relevant data, abstracted from experiments 2, 3, 4 and 5 in the two quoted sources<sup>4,5</sup>, are given in Table 1.

It seems unlikely that these findings are dependent on serological differences between the two challenge strains. Rather they may be explained by differences in growth rate of the two strains: on artificial culture media, 353/Z grows more slowly than W.18-323, and this may apply also to growth in mouse brain. Unpublished observations of mine support this hypothesis: out of 204 normal mice which received an intracerebral injection of 353/Z, in a dose sufficient to kill about 70 per cent of the mice within three weeks, the average time of death was 11.3 days after injection, but with W.18-323 it was only 9.6 days. Moreover, in experiments to determine the virulence of a single challenge strain, the average time of death was progressively reduced as the dose of injected organisms increased (Table 2). Presumably, reduction in the size of the inoculum injected *in vivo* has the effect of delaying growth of the bacteria just as it does in artificial culture *in vitro*.

Table 2. INFLUENCE OF DOSE OF INJECTED BACTERIA ON TIME OF DEATH OF NORMAL MICE\*

Dose of bacteria (No. of organisms of strain W. 18-323)	80	400	2,000	10,000
Average time of death† (days after injection)	11.0	10.4	9.8	8.9

\* Total of thirty-four mice injected with each dose of bacterial suspension.

† Excluding mice which survived for 21 days.

It was noteworthy, however, that even with a slow-growing strain or with a small inoculum very few mice died after the fourteenth day—suggesting that by then they had developed their own active immunity which enabled them to eliminate any surviving bacteria. The mortality in mice which received eighty organisms of strain W.18-323 (Table 2) was only 10 per cent, and a further reduction in the size of the inoculum would result in complete survival rather than increasing the average time of death (for those which died) beyond about 11 days. This is consistent with the following results obtained in mice which were protected with factor-1 serum before intracerebral challenge, if one assumes that the antiserum would be acting virtually by reducing the size of the inoculum. In the same series of experiments as those mentioned in the previous paragraph, a total of 204 mice

were injected intraperitoneally with factor-1 serum and subsequently challenged intracerebrally with the same dose of strain 353/Z as that given to normal mice; the average time of death remained at about 11 days (actually 10.8 days), as it was with normal mice, but the mortality was reduced by about 80 per cent. For a similar challenge of immunized mice with strain W.18-323, the average time of death increased from 9.6 days (for normal mice) to 10.9 days for these immunized mice, but the mortality was reduced by only about 50 per cent. With the slow-growing strain (353/Z) death takes place in unprotected mice as late as it is possible for it to occur; if the size of the challenge dose is reduced by previous immunization then the mice will tend to survive; immunization against this challenge strain will be very effective. With the fast growing strain (W.18-323), however, immunization may merely delay death, and a smaller proportion of mice will be completely protected—immunization against this challenge strain will be much less effective in terms of eventual survival.

### Experimental Bone Tumours caused by Common Viruses

ATYPICAL osseous and articular lesions have been observed in children in the course of measles and viral neuroinfections<sup>1,2</sup>. Although no viruses were isolated from the bones of the patients, the observations prompted the following investigation of the influence of viruses on bone tissue. In this communication we present the results of experiments with the ornithosis virus O.A.P. strain Y.S. 224, Coxsackie A<sub>1</sub>, Coxsackie B<sub>1</sub>, B<sub>2</sub> and B<sub>4</sub> viruses. The method used has been described before<sup>3</sup>. The experimental suspensions were free from bacterial contamination, as checked by inoculating various culture media. White mice of the 'Porton' race weighing 15 g each were used in the experiments. The suspensions were injected into bone marrow or joints. The Coxsackie A and B viruses were used in 25 per cent carcass suspensions, and the ornithosis virus in 15 per cent brain suspensions. The numbers of animals inoculated, the dosage of the suspensions and the frequency of lesions in the bones are shown in Table 1. Mice were anaesthetized in groups at intervals of 5 days, and inoculated parts were removed for histological examination. (The material was decalcified with 7 per cent nitric acid, fixed in paraffin, and stained with haematoxylin and eosin). In two mice, 25 and 35 days after inoculation, rapidly growing tumours were observed on the temporo-frontal aspect of the head in one case, and on the front limb in the other. The longest period of observation was 50 days.

The histological changes in the bones of the mice which had been inoculated with viruses were situated mainly in the metaphyses (Coxsackie B<sub>1</sub>, B<sub>2</sub>, B<sub>4</sub> and ornithosis),

Table 1				
Strain	No. of mice inoculated	Doses of suspension (ml.)	Virus titre	Frequency of osseous lesions
Ornithosis	50	0.03	<i>L.D.</i> <sub>50</sub> 10 <sup>-2</sup>	33 (66%)
Coxsackie A <sub>1</sub>	50	0.03	10 <sup>7.2</sup> in 1 ml.	34 (68%)
Coxsackie B <sub>1</sub>	30	0.03	10 <sup>6.2</sup> in 1 ml.	15 (50%)
Coxsackie B <sub>2</sub>	30	0.03	10 <sup>6.2</sup> in 1 ml.	17 (56.6%)
Coxsackie B <sub>4</sub>	30	0.03	10 <sup>6.15</sup> in 1 ml.	12 (40%)
Control suspension	80	0.03	—	0

epiphyses and metaphyses (Coxsackie  $A_9$ ), and rarely in the diaphyses (Coxsackie  $A_9$  and ornithosis). After infection with the Coxsackie  $A_9$  virus, the changes were multilocal in most of the mice, representing the same developmental stage.

In the initial stage of the disease, viruses produced haemorrhages and focal oedema in the bone marrow. The haemorrhagic changes were followed by focal necrosis of bone marrow cells and bone necrosis. The periosteal cells or endothelial cells lining the Haversian canals showed signs of proliferation and produced large numbers of undifferentiated mesenchymal cells with hyperchromatic nuclei. These cells were able to produce osteoid, which was arranged in strands in the bone marrow cavity, at the sites of destruction of bone and elsewhere (Figs. 1-2). The osteoidal tissue calcified, producing chaotically arranged osseous trabeculae, which sometimes resembled wickerwork. These pathological bone trabeculae sometimes invaded the muscles surrounding bone (Fig. 3). In these bone tumours large groups of red blood cells were observed, often not surrounded by vascular endothelium; sometimes newly produced small vessels were present. These capillaries were situated at right angles to the corticalis. The changes were accompanied by thickening of the external periosteum, not infrequently at some distance from the tumour. The muscles near the tumour

Fig. 1. Coxsackie  $A_9$ . Section from the diaphysis of the femoral bone and bone marrow cavity. Mesenchymal cells arising from the internal periosteum, producing osteoid, which calcifies and assumes the structure of chaotically arranged bony trabeculae in the marrow cavity. (Haematoxylin and eosin,  $\times 210$ .)

Fig. 2. Coxsackie  $A_9$ . Section from the temporal bone showing bone tumour invading the temporal muscle. The diploe of the primitive bone and intertrabecular spaces is filled with connective tissue and fusiform cells. Small blood vessels can be seen. (Haematoxylin and eosin,  $\times 90$ .)

Fig. 3. Ornithosis. Section from the diaphysis of the tibia. In the region of the destroyed compact bone of the diaphysis, chaotically arranged and freshly formed bony trabeculae invade the muscle. Primitive round osteoblasts are scattered among the trabeculae. (Haematoxylin and eosin,  $\times 90$ .)

Fig. 4. Ornithosis. Section of muscle neighbouring with the bone tumour, showing lumpy degeneration of the muscle, and proliferation of connective tissue cells with hyperchromatic nuclei. (Haematoxylin and eosin,  $\times 300$ .)

Fig. 5. Coxsackie  $A_9$ . Section of the liver. Cells surrounding and penetrating into the focus of hepatic necrosis have bizarre, hyperchromatic nuclei. (Haematoxylin and eosin,  $\times 300$ .)

showed a lumpy breakdown of muscle fibres and proliferation of the cells of the connective tissue (Fig. 4). Similar cells were observed in necrotic areas in the livers of mice inoculated with Coxsackie  $A_9$  viruses. The nuclei of these cells had bizarre shapes (Fig. 5).

The cavities of the knee joints in animals with lesions of epiphyses showed necrosis of epiphyseal cartilage, oedema of the ligaments, thickening of the synovial membrane, and sometimes filling of the articular cavity with loose, richly vascularized connective tissue. The lymph nodes of the extremities showed hyperplasia, cellular dissociation and focal necrosis, giving rise to the appearance of plaques in tissue cultures. No differences were found between the lesions in mice inoculated into the bone marrow and into the joints.

On the basis of the results obtained in these conditions, it can be concluded that the Coxsackie B<sub>1</sub>, B<sub>3</sub>, B<sub>4</sub> and A<sub>1</sub> and ornithosis O.A.P. strain Y.S.224 viruses injected into the bone marrow or joints in mice induce osseous tumours which originate in the connective tissue. We anticipate that further experiments will allow their classification and valuation of their malignity.

## Use of Kieselguhr to increase Cell Production for Animal Virus Investigations

ONE of the difficulties involved in elucidating the structure of an animal virus is to produce sufficient virus for investigation. Wheatley<sup>1</sup> has shown that the yield of cells given by mice inoculated with Ehrlich ascites tumour could be increased by previous injection of a suspension of kieselguhr. Krebs ascites tumour cells, propagated in mice, can later be used for growing virus *in vitro*<sup>2</sup>. We show that kieselguhr can also be used to increase the yield of these cells, and furthermore, the latter resemble those produced in the conventional way in their response to virus infection. A simple method is thus available to provide larger quantities of cells for later virus investigations.

Krebs II ascites tumour cells, obtained originally from Dr. D. C. Roberts, were maintained by weekly intraperitoneal injection of  $1 \times 10^7$  cells in 0.1 ml. of phosphate buffered saline (PBS) into genetically heterogeneous white mice. Either 0.2 per cent suspension of kieselguhr in PBS, or of PBS alone (0.1 ml.), was injected at the same time as the ascites cells. After 7 days the cells were withdrawn from both kieselguhr treated and control mice, washed to remove red blood cells by centrifugation and the cells counted; the percentage of cells permeable to stain was estimated with 0.2 per cent nigrosin in PBS.

Kieselguhr treated mice produced about 1.5 times as many cells as controls (Table 1). This figure, which supports the work of Wheatley<sup>1</sup>, would be slightly higher if uncounted cells only were considered. Furthermore, ascitic fluids from kieselguhr treated mice contained fewer red blood cells and the ascites cells thus required fewer washes to prepare for use.

Table 1. EFFECT OF KIESELGUHR ON PRODUCTION OF KREBS ASCITES TUMOUR CELLS

Treatment	Cells/mouse $\times 10^{-3}$	Percentage stained	Ratio of kieselguhr to control cells	No. of mice
Kieselguhr	6.1	9.9	1.6	7
Control	3.8	16.0		7
Kieselguhr	4.9	8.9	1.3	27
Control	3.8	6.4		27
Kieselguhr	7.3	9.6	1.4	37
Control	5.1	13.8		37
Kieselguhr	7.2	10.6	1.7	37
Control	4.3	10.9		37

Both kinds of cells were tested for their ability to support virus multiplication by infecting them with encephalomyocarditis (EMC) virus<sup>2</sup>. Virus yields, estimated both by haemagglutination and by plaque assay using Krebs ascites cells (from mice not given kieselguhr) in agar suspension<sup>2</sup>, were the same, within the limits of experimental error, whether the ascites cells came from kieselguhr or from untreated mice (Table 2). Mice injected with kieselguhr gave on average 1.5 times as many cells (Table 1) and so there would be a 1.5-fold increase in virus output from the same number of mice.

Table 2. COMPARISON OF VIRUS YIELDS IN CELLS FROM KIESELGUHR TREATED AND CONTROL MICE

Treatment	Plaque forming units/ ml. $\times 10^{-4}$	Haemagglutination units/ml. $\times 10^{-4}$
Kieselguhr	1.1	8
Control	0.9	8
Kieselguhr	2.3	16
Control	1.6	16
Kieselguhr	2.8	32
Control	3.4	32

The sensitivity of ascites cells from kieselguhr treated mice when used for plaque assay of EMC virus was compared with control mice using two virus preparations. The number of plaque forming units detectable was the same, within the limits of experimental error, when either type of cell was used (Table 3).

Table 3. COMPARISON OF ASCITES CELLS FROM KIESELGUHR TREATED MICE AND CONTROLS FOR PLAQUE TITRATION

Treatment	Plaque forming units/ ml. $\times 10^{-4}$	Large plaque Small plaque
Kieselguhr	4.6	1.00
Control	4.1	1.04
Kieselguhr	5.7	1.15
Control	6.0	1.10

The virus preparations used contained mutants differing in plaque size. The sensitivity of the two types of cells was the same for both large and small plaques (Table 3).

We thank Dr. F. Kingsley Sanders for his interest and constructive criticism and Dr. D. N. Wheatley for advice on the use of kieselguhr.

## PHYSIOLOGY

### Ultrastructure of the Membrane of Synaptic Vesicles

INVESTIGATIONS by Whittaker and Sheridan<sup>1</sup> on permanganate fixed preparations of isolated synaptic vesicles have recently confirmed that the membrane of such organelles has the structure of a "unit membrane"<sup>2</sup>, but have also indicated that in this case the classical model should be corrected in order to take into account the results obtained on negative stained specimens which suggest a membrane structure consisting of two 40 Å layers with an intermittent hydrophilic space between them.

In the course of experiments initiated with the aim of investigating possible morphological differences between synaptic vesicles and the axonic vesicles which are found in non-synaptic regions of peripheral nerves, we observed that in tissue specimens fixed in glutaraldehyde followed

by osmic acid the membrane of both kinds of organelle displayed a globular structure, which appeared to be more complex than either that of the unit membrane or that proposed by Whittaker. The results of observations on synaptic vesicles of frog cerebral cortex are briefly reported in this communication.

The frogs were pithed at room temperature (20°–21° C), and as soon as the brain was uncovered chilled phosphate buffered 4 per cent glutaraldehyde was poured over its surface. Small pieces of cerebral cortex were quickly removed, fixed in more of the same fixative, and treated with osmic acid after 2–16 h<sup>3</sup>. 'Epon' was used for embedding<sup>4</sup>. The sections were stained with lead monoxide<sup>5</sup>.

In cross-sections (Fig. 1) the membrane of synaptic vesicles appears to consist fundamentally of a single layer of globules with a thin electron dense contour and a light core. The size and the shape of such globules appear to vary from small spheres 40–45 Å in diameter, which are the most frequent, to larger ovoids measuring up to about 60 Å × 90 Å. The globules are connected to each other directly or through an osmiophilic granule; occasionally smaller globules form thin (about 20 Å) electron lucid bridges between globule and globule, giving them the aspect of a string of beads.

In face-on view (Fig. 1) the membrane of synaptic vesicles shows rather regular geometric designs amidst regularly and irregularly arranged globular structures. They appear to be polygonal (probably hexagonal) or round areas of unstained material limited by thin os-

miophilic lines and containing in their centres an osmiophilic granule. The diameter of such structures is about 90–110 Å, the central granule measuring about 20–30 Å. In cases in which the section is favourably oriented, the whole surface of synaptic vesicles appears to consist of an orderly mesh of such geometric designs, similar to mosaic floor. Frequently, however, thin osmiophilic septa can be resolved in the electron lucid area of such polygons, which therefore seem actually to be constituted by a rosette of non-stainable globules surrounding the central osmiophilic granule. The number of such globules is usually six in each rosette and their diameters range from 35 to 40 Å. On the basis of the observations in face-on views of the vesicles, we suspect that the large globules observed in cross-sections of the membrane are actually be polygonal units seen in oblique projections.

In conclusion, the reported observations seem to suggest that the membrane of synaptic vesicles is mainly formed by polyhedral units (probably hexagonal prisms), each consisting of a central osmiophilic granule surrounded by six osmiophobic globules, the base of the prisms being at tangent to the surface of the vesicle.

The relation of this electron microscope appearance of the membrane to the real structure cannot, of course, be resolved merely on the basis of these observations. Apart from the problem of the effects of fixation and dehydration on the tissue, there is the important problem of the size of the contribution of the embedding medium to the images obtained from sectioned material at high magnifications. In any case, the possibility that the described structure of the membrane is not the result of an artefact is supported by recent reports which propose that some biological membranes have a globular structure, by other reports which describe a hexagonal pattern in some other membranes, and by published pictures which were interpreted as showing a unit membrane structure, but a compatible with our proposed interpretation of membrane structure. Thus, Sjöstrand described a globular structure in mitochondrial membranes and in some cytoplasmic membranes of tissues fixed in potassium permanganate<sup>6</sup> and subsequently confirmed this finding in frozen dried tissues<sup>7</sup>. Nilsson described a similar globular structure in cross-sections of the outer segment disk membranes of tadpole retina fixed in osmium tetroxide<sup>8</sup>. On the other hand, hexagonal structures with a central dense spot were observed by Robertson<sup>10</sup> in face-on views of positively stained synaptic disks of Mauthner cells of the goldfish (Robertson also reported seeing a "suggestion" of a similar pattern in synaptic vesicles of the same cells). Moreover, hexagonal structures were recently described by Benedetti and Emmelot<sup>11</sup> in negatively stained isolated plasma membranes of rat liver seen in face-on views. The diameter of such polygonal structures was 95 Å in the case of Robertson's material, and 90 Å in the case of the material of Benedetti and Emmelot. Also a picture of Murray<sup>12</sup> of a face-on view of a negatively stained preparation of isolated cell membrane of *Micrococcus sarcin* shows a similar hexagonal pattern. Furthermore, we think that the cross-sections of the membrane of positively stained synaptic vesicles in the pictures given by Robertson<sup>10</sup> and by Whittaker and Sheridan<sup>1</sup> may be interpreted as showing a polyhedral-globular structure rather than a unit membrane structure. Moreover, the polyhedral-globular model may provide an explanation for the apparent differences in membrane thickness among vesicles that can be observed in the pictures of negatively stained isolated vesicles published by Whittaker and Sheridan, although no explanation for this appearance was suggested by these authors: the membrane shows a diameter of 45–50 Å when actually seen in profile, while showing a diameter of about 90 Å in face-on view. In addition, the apparent intermittent splitting of the membrane by the phosphotungstate stain, which has been observed in such pictures where the membrane shows a diameter of about 90 Å or more, could possibly be explained

Fig. 1. Electron micrograph of frog brain cortex. The synaptic vesicles are bound by a membrane which in cross-section appears to consist of a chain of electron lucid globules (arrows). Sometimes an osmiophilic granule is interposed between two adjacent globules ("X" marks). Often, osmiophilic granules constitute the centre of clear areas limited by an osmiophilic contour (interrupted arrows). Such designs are interpreted as features of face-on views of the membrane. A similar structure is also visible in the axolemma (in the square); in this case thin septa can be seen reaching from the central granule to the osmiophilic contour and dividing the clear area into five or more globules. (Scale line = 500 Å.)

plained on the basis of an accumulation of stain in the central osmiophilic area of the hexagonal prisms seen in face-on view (rather than as due to penetration of stain into the middle layer of a unit membrane seen in cross-section, as suggested by Whittaker and Sheridan).

Osmiophobic globules in the described polyhedral-globular structure probably require a micellar arrangement of the membrane lipid. It is noteworthy that such an arrangement, as well as the formation of hexagonal patterns, has been shown to occur in reconstituted phospholipid-water systems by X-ray diffraction and electron microscope techniques<sup>13-15</sup>.

Polyhedral-globular units can also be observed in the membranes of mitochondria, as well as in other membranes, including the axolemma (Fig. 1), of our preparations of frog brain.

I thank Dr. M. K. Horwitt for his generous help and encouragement, and Dr. J. F. Hartmann for his advice. This investigation was supported by the Illinois Mental Health Fund.

## Colour Vision in the Virginia Opossum

COLOUR vision in mammals has long been considered to be restricted to primates, possibly as a result of independent evolution of the ability after it was lost during a nocturnal stage of mammalian evolution<sup>1</sup>. A variety of investigations, however, have indicated some ability to discriminate on the basis of colour in the European red squirrel<sup>2</sup>, the pigmy goat, red deer, and Nilgai antelope<sup>3</sup>, the Masai giraffe<sup>4</sup>, the common cat<sup>5</sup>, and the antelope ground squirrel<sup>6</sup>. Because the Virginia opossum (*Didelphis virginiana*) is very similar to the earliest known mammals<sup>7</sup>, the presence or absence of colour vision in this species would be of particular relevance to theories of the phylogeny of colour vision in both marsupial and placental mammals. The marsupial eye is essentially like that of a placental mammal in structure, while the retina is basically a reptilian one containing single and double cones bearing oil-droplets and a large number of filament rods. In particular, the opossum has a clearly nocturnal eye and some of the single cones lack oil-droplets and are similar to the cones of placental mammals<sup>8</sup>. A further consideration is that the marsupials are the only class of vertebrates having double cones in the retina (fish, amphibians, reptiles, and birds being the others) which have not yet been shown to have colour vision<sup>9</sup>.

The subjects were two adult female littermates from a locally caught mother, raised in the laboratory and quite tame. The taming procedure has been described elsewhere<sup>10</sup>. The apparatus is essentially the same as used previously to test position reversal learning in the opossum<sup>11</sup>. The start box opened into a choice chamber 60 cm long at the end of which were the two stimulus

panels. Each panel contained a circle of translucent plastic (3.8 cm in diameter) which was illuminated from the reverse side. The room was in darkness during the trials. The required response was to touch the nose to the stimulus; if the correct stimulus was selected, the panel was released manually and pivoted upward making available a pellet of 'Hunt Club' dog food in a cup in the floor (food was present behind each stimulus on all trials). After the pellet was taken, the panel was returned and both stimuli left in position as the subject finished eating. A heavy masking panel was then lowered, covering both stimuli. After an incorrect choice, the masking panel was lowered immediately. Lowering this panel also turned off the stimulus lights and turned on dim box and room lights. After the first few days, the subjects spontaneously returned to the start box on most trials.

Table 1. ORDER OF PRESENTATION (O.P.) AND DAYS TO CRITERION (DAYS) FOR EACH PROBLEM FOR EACH SUBJECT

Problem	Subjects		Subjects	
	First opossum O.P.	Days	Second opossum O.P.	Days
R-B	1	9	1	5
R-G	2	5	4	2
R-Y	3	6	6	2
Y-B	4	3	2	7
Y-G	5	15	5	5
G-B	6	10	3	65†
Grey*	7	35	7	18

\* Grey was paired with each of the four colours on each day.

† The subject was sick and eating erratically during most of this period.

R, Red; B, blue; G, green; Y, yellow.

The stimuli were produced by Kodak 'Wratten' filters (red No. 25, yellow No. 15, green No. 58, and blue No. 47), which are relatively broad and roughly divide the visual spectrum into four segments. They were equated for brightness for the human eye by adding neutral density filters to adjust the red, yellow, and green filters to the equivalent brightness of the blue. Neutral filters (1.0, 0.7, 0.3, and 0.0 log units in density) were paired with the colour filters on all trials in a variable fashion in all combinations such that the stimuli on a given trial could be equally bright or dim or differ in intensity by as much as 10:1. The side of the correct stimulus was determined by Gellerman series<sup>12</sup> which were changed at every session. The lighting system for each side consisted of two 'G.E.' No. 656 bulbs of 6 W and side by side 5 cm from the stimulus panel. The filters were placed in front of the light with the colour filter closest to the panel and no lens or reflecting system was used. The resulting stimulus patch was homogeneous and approximately 5.5 foot lamberts in brightness (based on 'Macbeth Illuminometer' measurements). The translucent plastic stimulus circles also prevented the subjects from being able to smell the colour filters directly. Each daily session consisted of twenty trials using a modified correction procedure: after a correct response, the colour and neutral density filters were placed according to the day's schedule; but after an error, the correction trial consisted of the same filter arrangement and this was repeated until a correct response was given. Thus eventually a correct response was given to each stimulus pair during a daily session and twenty reinforcements were thereby obtained. Only the first response to a stimulus pair was counted in the scoring since, after an error, the subject needs only to change sides to be correct. Each daily session therefore consisted of twenty scheduled trials and a variable number of corrections. Thus responding to an inappropriate cue (for example, position or brightness) could lead to a perseveration of errors and selective extinction of that response.

Both opossums learned to discriminate each colour from each of the other colours to a criterion of thirty-five out of forty correct in two consecutive sessions of twenty trials each ( $P < 0.001$ ). Table 1 gives the order of presentation of each problem and the number of training days to criterion. The first discrimination trained was blue versus red and learning for both subjects was rapid, requiring 180 for the first and 100 scheduled trials for the second opossum.

Even with the 10:1 variation in brightness provided by the neutral density filters, the possibility exists that the opossum is markedly deficient in sensitivity to the longer wavelengths. It is therefore particularly interesting that, after this training, transfer was readily shown by the second opossum when the problem was changed from blue versus red\* to blue versus yellow (eighteen out of twenty correct on the first day).

In this task, the relative wavelength of the positive and negative stimuli was kept constant in all problems for a given subject. For the first opossum the longer wavelength stimulus was always positive and vice versa for the second. With regard to specific problems, this meant that after red and yellow, the next problem scheduled was yellow and blue, and transfer was good with sixteen out of twenty correct choices on the first day. In previous testing with other subjects, an attempt was made not to change the value of a given stimulus in successive problems such that, after red and yellow, the next problem would have been blue and yellow, and this design led to markedly retarded learning. These findings suggest that the opossum discriminated between colours in a relative rather than an absolute fashion.

The final test given both subjects was to learn to discriminate between all colours and a grey stimulus. The grey stimulus, equated in brightness to the colour filters, was used with the neutral density filters in the usual fashion. Each daily session consisted of four blocks of five trials each with each block using a different colour. The order of colours used varied from day to day, and the coloured stimulus was always positive. The criterion here was sixty-eight out of eighty trials ( $P < 0.001$ ) involving twenty of each colour, with the additional restriction that no more than three errors are given to a particular colour. The initial performance of both subjects on this task was interesting: they consistently approached the stimulus that had been always positive in the preceding series (for example, red for the first opossum) and avoided the colour that had been negative. The yellow and green were responded to in an intermediate manner so that the grey stimulus seemingly was in the middle of the group of colours. Both subjects reached criterion on this problem, but it required considerable training (35 days for the first opossum, 18 days for the second). Apparently, learning of the preceding relative discrimination between colours did not aid the acquisition of the absolute discrimination of grey versus any colour. After this criterion was met the subjects were tested for an additional day using the four colours in random order against grey, and they made seventeen and eighteen correct choices respectively. Successful performance on this last task indicates that the ability of the opossum to discriminate colours cannot be explained by differential brightness of the various colours or by the stereo-colour mechanism suggested by Kohler<sup>13</sup> by which aberrations in the lens of the two eyes may result in different binocular depth cues for different colours.

A learning criterion of twenty-nine out of forty would be statistically significant at the 0.01 level, but if the opossum can gain some selective advantage from perceiving colours (which might account for the retention of this ability in a primarily nocturnal animal), then somewhat better performance should be obtainable. Errorless performance was not expected in view of the opossum's limited learning ability<sup>14</sup>, and the possibility that the least bright stimuli, particularly the red, may be nearly imperceptible to the opossum.

During the preliminary work in this series, a cat was also run as described above except that the reinforcement was ground horse meat. The animal was adapted to the laboratory and had been previously used successfully in an auditory discrimination experiment. During 10 days with twenty scheduled trials a day on a yellow-blue discrimina-

tion, the number of correct choices ranged from eight to twelve with no sign of any learning. The opossums, in contrast, usually made at least thirteen correct responses and only once had as few as eleven correct. This indicates that no striking artefacts were present and that the colour vision of the opossum is more readily employed than that of the cat.

The finding of colour vision in the opossum has some interesting implications: (a) the earliest placental mammals, which very closely resembled the opossum and were probably also nocturnal<sup>15</sup>, could similarly have retained colour vision derived from their reptilian ancestors; (b) the colour vision found in a wide range of placental mammals indicates a widespread capacity (most highly developed in the primate line); this supports the view that the colour vision of primates is a primitive mammalian characteristic; (c) because the opossum is closely related to the ancestor of the Australian marsupials<sup>16</sup>, colour vision may well be found in these animals also.

Some preliminary investigations were carried out at Duke University under the support of grants from the U.S. National Science Foundation to R. P. Erickson and from the U.S. National Institute of Mental Health to N. Guttman. I thank Kenneth Ley for helping with the training.

## Parolfactory Vesicles as Photoreceptors in a Deep-sea Squid

THE recent finding<sup>1</sup> that the parolfactory vesicles of *Loligo* have the structural and biochemical properties of photoreceptors prompts this preliminary communication on the organization of these organs in a cranchid squid, *Liocranchia* sp. (see ref. 2).

*Liocranchia* is a small oceanic form (about 80 mm dorsal mantle length) which occurs at depths as great as 2,500 m. It has typical cranchid features as well as thirteen photophores round each eye. These were first described by Chun<sup>2</sup> and were also observed here: it is emphasized that their structure, which is typical of a light-producing organ, is distinct from that of the organs now described for the first time. This description is based on material collected by the *Discovery* expedition and kindly supplied by Dr. M. Clarke. Unfortunately, no material suitable for electron microscopy is available. The material was fixed with formol, stained by a Cajal silver method<sup>3</sup> and serially sectioned at 15 $\mu$ .

In the transverse plane the brain is seen to be organized in a manner typical of decapod molluscs (Fig. 1): the large, paired optic lobes lie close to the central brain, with which they are connected by the optic tracts. Associated with these tracts are several nervous and non-nervous structures<sup>4,5</sup>, the peduncle lobe, the olfactory lobe, the optic gland, the subpedunculate tissue and the parolfactory vesicles. The first four structures are similar

\* The first colour mentioned is always the one which the subject is trained to choose, that is, it represents the correct choice.

in their gross morphology to their counterparts in *Loligo*<sup>6</sup>, but the last are different, both in their organization and in their more regular arrangement.

The vesicles form a row on each side of the central brain and between it and the optic lobe. Each row lies posterior to the optic tract and extends in the dorso-ventral direction from the dorsal and lateral margin of the olfactory lobe down past the suboesophageal lobe to join, in the ventral midline, with the contralateral row. There are twenty-four vesicles in each row. If the oesophagus is taken as the centre of the brain it will be seen that those in the centre of the row are elongated along a radial axis (Fig. 1), and are about 120 $\mu$  long, while those at the dorsal and ventral extremes tend to a more circular cross-section or are elongate along a tangential axis, and may be as much as 160 $\mu$  broad. A group of vesicles from the central region is shown in Fig. 2: in each, three regions can be distinguished: A, the pigmented cup; B, the processes; and C, the cell area.

The cup comprises a thin layer (2-3 cells thick) of cells full of black granules after staining with silver. Pigment is present only in the radial and medial walls, so that a pigmented cup is formed, the occluded opening of which is directed peripherally. Laterally, the vesicles are covered by the thin membrane that encapsulates the brain in cephalopods<sup>7</sup>. Medially, the pigment cup is distinct from the cell layer of the adjacent brain. No nerve fibres have been seen associated with the vesicles.

The processes form a predominantly parallel array, the long axis of which is parallel to the long axis of the cup (Fig. 2), which itself lies on a radial axis of the brain

(Fig. 1). In the central region of the chain the cluster of processes in each vesicle is about 70 $\mu$  long and about 40 $\mu$  wide. Under the light microscope at the highest power the processes appear tubular and can be seen to bear cross-striations (Fig. 3) at right angles to the long axis. This configuration invites comparison with the parolfactory vesicle in *Loligo*<sup>1</sup> or the epistellar body in *Eledone*<sup>8</sup>, both of which show processes with cross-striations in the light microscope, and both of which reveal a rhabdomic organization in the electron microscope<sup>9</sup>.

The cell area (Fig. 2), which occupies the peripheral end of the cup, contains a compact mass of cells, the round nuclei of which are about 5 $\mu$  in diameter. Nuclei are absent in the region adjacent to the processes (Fig. 3) and it is inferred that the basal regions of the processes lie here. With the present method it was not possible to distinguish different cell types within the cell area, but the cells are so numerous compared with the processes that some of them are presumably "accessory".

Within each vesicle the long axes of the processes are parallel to the radial walls of the pigment cup. The vesicles are so oriented that their axes diverge peripherally, and each chain of vesicles is so disposed that light could be collected over an arc of almost 180° (Fig. 1). If the processes do represent "rhabdomes", then they must be activated by light that has already passed through the peripheral cell area.

The position of these organs and their structure as seen in the light-microscope leaves little doubt that they are highly developed parolfactory vesicles. It seems likely that they are photoreceptors, although further evidence is

Fig. 1. The central brain and optic lobe of *Liocranchia*. Transverse section after Cajal silver stain, dorsal uppermost. b.d., dorsal basal lobe; b.l., lateral basal lobe; oes., oesophagus; olf., olfactory lobe; opt., optic lobe.

Fig. 2. Three vesicles. Cut and stained as for Fig. 1.

Fig. 3. The processes in one vesicle highly magnified. Note the cross-striations. Cut and stained as for Fig. 1.

required to be certain of this. Attention is drawn, however, to the elaborate nature of the vesicles in this genus when compared with *Sepia* or *Loligo*. First, they are more numerous and relatively larger than in *Loligo*. They are linked into a continuous chain, perhaps to maximize the collection of photons. Second, the processes are packed in an ordered array, instead of lying randomly as in *Loligo*<sup>9</sup>. Does such a parallel array serve to maximize the collection of light, when little light energy is available? Third, the vesicle here has a marked polarity. Fourth, pigment granules occur in the medial part of the vesicle wall.

Several questions present themselves. Are the parolfactory vesicles developed here in association with the low intensity of light in the habitat? Are they associated with the presence of photophores? Are they unique to the Cranchiidae? With fragmentary evidence it is possible only to speculate, but several other deep-sea and photogenic forms have been examined and only in one of them were the parolfactory vesicles especially well developed. This was *Bathotaurina* sp., also a cranchid and also photogenic. It is interesting that the parolfactory vesicles here are intermediate in form, in that they are larger than in *Loligo* and more asymmetrical, but they do not, like *Liocranchia*, possess a parallel array of processes. If well developed parolfactory vesicles are a feature of the Cranchiidae we have still to discover the peculiar feature of the organization of this group that demands this development.

The function of accessory photoreceptors situated deep within the body of an animal with well developed eyes has been considered by Nishioka *et al.*<sup>1</sup>. It is now clear that the parolfactory vesicles in cephalopods are not vestigial photoreceptors; nor can there be doubt that in this class of molluscs extra-ocular photoreception is widespread.

I thank Dr. Malcolm Clarke of the National Oceanographic Institute for supplying the material; and Professor J. Z. Young and Professors H. A. Bern and R. S. Nishioka for their comments on the manuscript.

### Release of Catecholamines in the Guinea-pig by Substances Involved in Anaphylaxis

MANY substances are released in anaphylaxis, including histamine<sup>1</sup>, bradykinin<sup>2,3</sup> and slow-reacting substance<sup>3-5</sup>. In some species, histamine<sup>6</sup>, bradykinin<sup>7-10</sup> and possibly slow-reacting substance<sup>11</sup> liberate catecholamines into the circulation, and so the anaphylactic reaction may also be expected to lead to catecholamine release, and some evidence suggests that it does<sup>5</sup>. This communication demonstrates directly that, in the guinea-pig, histamine, bradykinin, slow-reacting substance and anaphylaxis all liberate catecholamines into the circulation; their relative effects are estimated and their roles discussed.

We used a modification of the blood-bathed organ technique for detecting active substances in circulating blood<sup>12</sup>. Guinea-pigs of either sex weighing 500–1,050 g were anaesthetized with pentobarbitone sodium (60 mg/kg intraperitoneally). Cannulae were inserted into the trachea, into both jugular veins and into a carotid artery,

and heparin (3,500 U) was injected intravenously. The animal was then ventilated with air or oxygen by a miniature Starling respiration pump. Blood from the carotid artery was superfused at a constant rate between 2.1 and 2.5 ml/min over the assay tissues by a roller pump. The blood was returned to the animal through both jugular veins—to one through a second channel in the roller pump and to the other under gravity. The extracorporeal circuit contained 3–5 ml. of blood. To detect catecholamines, 2–5 cm lengths of rat stomach strip<sup>13</sup> and of chick rectum<sup>14</sup> were used. This combination of tissues is highly specific for catecholamines<sup>15</sup> and readily distinguishes between adrenaline and noradrenaline<sup>16</sup>. Isometric contractions of the muscles were transduced with Ether strain gauges, adjusted so that the tissues had an initial tension of approximately 3 g. Arterial blood pressure and intratracheal pressure were transduced with Statham gauges connected to side tubes on the carotid and tracheal cannulae; rectal temperature was transduced with a thermistor. All records were displayed on an eight channel Beckman Offner dynograph. Drugs were injected either intravenously into a jugular vein or through a fine nylon catheter passed down the left carotid artery to the arch of the aorta. The position of the catheter was checked *post mortem*.

To prepare the slow-reacting substance in anaphylaxis, the lungs were excised from guinea-pigs previously sensitized to ovalbumen, and perfused through the pulmonary artery for 60–75 min at 1.25–1.75 ml/min with antigen (4 mg/ml. of ovalbumen) in Tyrode containing cysteine (1.2 g/l.) and succinic acid (120 mg/l.). Freeze-dried slow-reacting substance was prepared from the perfusate, after removal of histamine and some other impurities. Slow-reacting substance prepared in this way had previously been shown to be substantially free from acetylcholine, angiotensin, bradykinin, histamine, 5-hydroxytryptamine, prostaglandin F<sub>2α</sub> and substance P, and to differ from the "slow-reacting substance in anaphylaxis" of Brocklehurst<sup>4</sup> in that they have a bronchoconstrictor effect in the guinea-pig<sup>17</sup>. Two control samples for the experiments with this slow-reacting substance were prepared in exactly the same way as the substance except that, in one, the lungs were taken from unsensitized guinea-pigs and, in the other, the perfusion fluid did not contain antigen.

Intravenous injection of histamine, bradykinin or slow-reacting substance liberated a burst of catecholamine into the circulation, as shown by relaxation of the blood-bathed organs. The catecholamine was mainly, if not all, adrenaline, because the extent of the relaxation of the rat stomach strip, relative to that of the chick rectum, could be exactly matched by intravenous injection or infusion of adrenaline. The amount of adrenaline liberated increased with increasing dose of histamine, bradykinin or slow-reacting substance. The following estimates were obtained of the dose of each agent required to give a relaxation of the assay tissues to the same degree as that produced by 0.1 µg of adrenaline: histamine, 4.4 µg (range 2–5 µg in fourteen experiments); bradykinin, 0.75 µg (range 0.1–2 µg in twelve experiments); slow-reacting substance, 1.5 mg (range 0.5–6 mg in fifteen experiments). After a single intravenous injection of bradykinin, histamine or slow-reacting substance, release of adrenaline sometimes lasted for 10–15 min. The two control samples were inactive at two to three times the dose at which slow-reacting substance liberated adrenaline (Fig. 1). After exclusion of the adrenal glands from the circulation, doses of histamine, bradykinin or slow-reacting substance that had previously been effective in the release of adrenaline were ineffective, indicating that the adrenal glands were the source of the catecholamines detected in the circulation.

Ovalbumen (0.05–0.5 mg given intravenously) liberated adrenaline in sensitized guinea-pigs (Fig. 2), whereas it was ineffective in animals that had not been sensitized to it. This release lasted for 15 min to > 60 min and cor-

responded in intensity to an intravenous infusion of  $0.02-1 \mu\text{g}/\text{min}$  of adrenaline. When the adrenal glands were excluded from the circulation, antigen no longer released adrenaline into the blood stream. To test whether desensitization, rather than exclusion of the adrenals, explained the failure of the second dose of antigen to liberate adrenaline, three sensitized guinea-pigs were prepared, but the adrenals were removed from the circulation before giving antigen. Although these animals were very susceptible to ovalbumen ( $0.02-0.2 \text{ mg}$  given intravenously), as shown by intense bronchoconstriction followed by death, no catecholamine release was detected. The adrenals were therefore also the source of the circulating adrenaline released by antigen.

When histamine, bradykinin, slow-reacting substance or antigen was given intravenously, a rise in intratracheal pressure (taken to indicate bronchoconstriction) preceded the relaxation of the blood-bathed organs and a return towards normal pressure accompanied the appearance of catecholamines in the extracorporeal circulation. When bradykinin or histamine was injected into the aorta, the

Fig. 1. Guinea-pig (1,030 g) anaesthetized with pentobarbitone (60 mg/kg intraperitoneally). The tracing shows the movements of a rat stomach strip (R.S.S.) and chick rectum (C.R.) superfused with carotid arterial blood from the guinea-pig. Carotid blood pressure (B.P.) in mm of mercury, intratracheal pressure (I.T.P.) in cm of water and time in min. All doses are intravenous; the system is calibrated with single doses or infusions of adrenaline (A). Slow-reacting substance (SRS-A) raised intratracheal pressure and liberated adrenaline, but the control samples for this substance (C1 and C2) did not, even when the dose was increased to 5 mg. Administered directly to the blood-bathed assay tissues as a control, slow-reacting substance had little effect on chick rectum, but caused rat stomach to contract.

Fig. 2. Guinea-pig (540 g), previously sensitized to ovalbumen, anaesthetized with pentobarbitone (60 mg/kg intraperitoneally). Records are arranged and labelled as in Fig. 1. An intravenous dose of ovalbumen (EA, 0.2 mg intravenous) raised the intratracheal pressure and the blood pressure. There was also a prolonged release of adrenaline, equivalent to more than an intravenous infusion of  $0.2 \mu\text{g}/\text{min}$ . The release stopped when the adrenal glands were excluded from the circulation. Administered directly to the blood-bathed assay tissues as a control, ovalbumen had no effect.

Fig. 3. Guinea-pig (825 g) prepared and records arranged and labelled as in Fig. 1, except that some doses are intra-arterial and all are in  $\mu\text{g}$ . Intravenous doses of bradykinin (B) raise intratracheal pressure and liberate adrenaline; intra-arterial doses of bradykinin liberate adrenaline without raising intratracheal pressure. Administered direct to the blood-bathed assay tissues as a control, bradykinin had no effect on chick rectum, but caused rat stomach to contract.

release of adrenaline could be observed without accompanying bronchoconstriction; but, with slow-reacting substance or antigen, release of adrenaline was always accompanied by bronchoconstriction. Fig. 3 illustrates these actions of bradykinin by both routes of injection.

Figs. 1, 2 and 3 show that liberation of adrenaline is often accompanied by a rise in blood pressure. In several experiments, the rise in blood pressure produced by histamine, bradykinin, slow-reacting substance or antigen was greater than would have been expected from the amount of adrenaline liberated, suggesting that there may also have been a sympathetic nerve stimulation. Indeed, both histamine<sup>18</sup> and bradykinin<sup>19</sup> have been shown to excite ganglia. If anaphylaxis also leads to sympathetic stimulation, the bronchoconstriction would thereby be reduced; some evidence for this is provided by the fact that propranolol is more effective than adrenalectomy in potentiating anaphylactic bronchoconstriction in the guinea-pig<sup>20</sup>.

The liberation of adrenaline by bradykinin, histamine or slow-reacting substance could arise from a direct or an indirect stimulation of the adrenal medulla. That hexamethonium (2-7 mg/kg given intravenously in two experiments) or pentolinium (5 mg/kg in three experiments) failed to block the release of adrenaline by bradykinin shows that, at least with bradykinin, the stimulation was not transmitted through a ganglionic pathway blocked by these drugs. Histamine, bradykinin and slow-reacting substance release adrenaline into the circulation of the guinea-pig, and these substances are liberated during anaphylaxis<sup>1-5</sup>, and so they could partly or wholly account for the release of catecholamine by antigen. Whatever the mechanism, there is no doubt that this release, coupled with any sympathetic stimulation that may also occur, will lessen the intensity of the bronchoconstriction. If histamine, bradykinin and (or) slow-reacting substance mediate the bronchoconstriction of human bronchial asthma, a partly compensating release of catecholamines may also be expected to occur. This expectation is strengthened by the finding that  $\beta$ -adren-ergic blocking agents intensify asthma<sup>21</sup>. Drugs given to mitigate asthma by antagonizing the bronchoconstrictor effect of an endogenous substance should therefore not, at the same time, block any liberation of catecholamine from the adrenal glands by that substance. The fact that antihistamine drugs block release of catecholamines by histamine<sup>6</sup> may help to explain their relative inefficacy in asthma.

Some or all of the endogenous substances shown here to release catecholamines into the circulation are believed to take part in local reactions to injury. The liberation of catecholamines by these substances may perhaps be regarded as a protective mechanism operating when the amount of mediator is excessive.

We thank Dr. W. A. Jones, Mr. G. G. Matthews, Mr. M. A. E. Palmer and Mr. W. J. F. Sweatman for help in preparing the slow-reacting substance, Dr. E. D. Nicholaides for synthetic bradykinin, and Mr. R. Wong for technical assistance. One of us (J. R. V.) thanks the Medical Research Council for a grant.

### Depressor Effects with Sympathomimetic Amines after Blockade of Cardiovascular $\alpha$ -Receptors

THE reversal of the pressor response to adrenaline after ergotamine was first observed by Dale<sup>1</sup> in cats. Reversal of the pressor effects of noradrenaline has also been observed after ergotamine or 'Dibenamine'<sup>2</sup>. Nickerson and Nomaguchi<sup>3</sup> demonstrated that directly acting catecholamines and indirectly acting sympathomimetic amines such as hydroxyamphetamine or tyramine lowered the blood pressure of cats after blockade of  $\alpha$ -receptors.

The depressor effect of noradrenaline in cats after blockade of  $\alpha$ -receptors has been attributed to an action on cardiovascular  $\beta$ -receptors<sup>4</sup>. The present experiments have been made in pithed rats and chloralosed cats using a number of directly and indirectly acting sympathomimetic amines to study further the site, mode of action and chemical structure of the molecules necessary to produce lowering of the blood pressure after blockade of  $\alpha$ -receptors.

After treatment with phenoxybenzamine or 'Hydergine', depressor effects were obtained in rats with the catecholamines (–)-noradrenaline, (±)- $\alpha$ -methyl noradrenaline, (–)-adrenaline, dopamine and epinine but not with (–)-phenylephrine which lacks the ring hydroxyl in the 4 position. The depressor effect only appeared if the mean carotid arterial blood pressure was greater than 65 mm of mercury, and the necessary sustained increase in vascular tone was achieved by giving ergotamine before phenoxybenzamine. In agreement with Nickerson and Nomaguchi<sup>3</sup>, molecules with *N*-alkyl or  $\alpha$ -carbon substituents (adrenaline,  $\alpha$ -methyl noradrenaline) had greater depressor potency than those lacking them (noradrenaline, dopamine, epinine). L-Dopa with an acidic and basic terminal also had depressor activity, but catechol which lacks the aliphatic side-chain did not have depressor

potency. Presumably, attachment to receptors through the cationic head was necessary for depressor as well as pressor activity. The depressor effects of the compounds were abolished by an antagonist at  $\beta$ -receptors, propranolol, and pressor effects then reappeared.

After ergotamine and phenoxybenzamine, the indirectly acting amines  $\beta$ -phenylethylamine or tyramine also elicited depressor responses and these were abolished by propranolol. The depressor effects of these indirectly acting amines were prevented by pretreating the rats with reserpine or cocaine, which deplete<sup>5</sup> or render inaccessible<sup>6</sup> the noradrenaline stores in sympathetic post-ganglionic nerves in circumstances which enhance the depressor effects of the directly acting noradrenaline.

Karim<sup>4</sup> suggested that the depressor response to noradrenaline which developed in cats following blockade of  $\alpha$ -receptors was caused by activation of  $\beta$ -receptors in the splanchnic blood vessels. In six cats, however, the depressor responses to noradrenaline and dopamine persisted unchanged either after evisceration which removed the splanchnic blood vessels, or after evisceration and ligation of the abdominal aorta immediately below the diaphragm which excluded the systemic circulation to the lower limbs and the lower half of the trunk. In a further four eviscerated cats, the circulation was confined to the heart and lungs by ligation of the carotids, the subelavians, the internal mammary arteries and the root of the aorta between the left first intercostal and subclavian arteries. Depressor responses were still elicited by dopamine and by noradrenaline after phenoxybenzamine, and pressor effects restored by propranolol.

These investigations showed for the first time that the depressor responses to directly and indirectly acting sympathomimetic amines which appeared after blockade of  $\alpha$ -receptors were caused by an action on cardiovascular  $\beta$ -receptors. The responses were influenced by the chemical structure of the amines and by the degree of vascular tone. The depressor responses to indirectly acting sympathomimetic amines  $\beta$ -phenylethylamine and tyramine were apparently mediated *via* noradrenaline release in a similar way to their normal pressor effects. The depressor responses to the sympathomimetic amines were a result of action on either the heart or the pulmonary vessels, the former being more likely.

This investigation was supported by grants from the Mental Health Research Fund and the Bethlem Royal and Maudsley Hospitals Research Fund respectively.

### Suppression of the Early Inflammatory Response in the Sheep by Strophanthin G

It is well established in rats that the increased vascular permeability which follows the intrapleural injection of turpentine is due to the local release of histamine and is continued by the activation of other mechanisms<sup>1,2</sup>. Our experiments on sheep have shown a similar pattern of immediate histamine release and later continuation of the increased vascular permeability. Following the report by Judah, Ahmed and McLean<sup>3</sup> of the similarity of action between the antihistamine promethazine and the cardiac glycoside strophanthin G, strophanthin G was used as a possible suppressor of the early inflammatory changes in the sheep.

Romney Cheviot X lambs weighing about 20 kg were used: they were "blued" by intravenous injection of pontamine blue (25 mg/kg body weight of a 5 per cent

solution in isotonic saline). Turpentine was used as the irritant to produce inflammation: the intradermal injection of 0.1 ml. of turpentine into the clipped back of "blued" sheep was followed by marked leakage of dye at the injection site. The size of the blue area varied from 3.5–5 cm in diameter at the end of 1 h. In "blued" sheep pretreated with the antihistamine mepyramine maleate (25 mg/kg body weight in 5 per cent solution, injected intramuscularly), the leakage of dye did not develop until 1 h after the intradermal injection of turpentine. Pretreatment of sheep with mepyramine maleate also suppressed exudate formation after the intrapleural injection of 0.5 ml. of turpentine into the right pleural space. The antihistamine treatment, however, failed to give complete suppression of exudate formation for longer than 2 h.

Histamine depletion using compound 48/80 gave similar results. Sheep were depleted of their stores of histamine by repeated injections of compound 48/80 using the method of Spector and Willoughby<sup>1</sup>; a 0.1 per cent w/v solution of compound 48/80 in saline was given intraperitoneally, morning and evening, in ten doses beginning with an evening dose. The dose used was 0.6 mg/kg body weight for the first eight injections and 1.2 mg/kg for the two final injections. Skin tests were carried out 2 h after the last injection. In sheep depleted of histamine both the early inflammatory changes in the skin and exudate formation in pleural cavity were suppressed. Compound 48/80, however, like mepyramine maleate, failed to suppress the inflammatory changes for longer than 1 h in the skin and 2 h in the pleural cavity. Pretreatment of sheep with strophanthin G (100 µg/kg body weight intravenously) suppressed the leakage of dye for 1 h after the intradermal injection of 0.1 ml. of turpentine, after which marked blueing took place. Pretreatment with strophanthin G also suppressed the formation of pleural exudate for 2 h after the intrapleural injection of turpentine. These results are similar to those observed with mepyramine maleate in the sheep.

These experiments show that a biphasic response of increased vascular permeability develops in the sheep after injury with turpentine, the first stage being inhibited by antihistamines. The antihistamine compound mepyramine maleate is a specific antagonist for histamine, and has not been shown to antagonize any other compound which increases capillary permeability<sup>1,4-7</sup>. In the sheep, the suppression of the early inflammatory changes by pretreatment with mepyramine maleate indicates that it is the local release of histamine which initiates the increased vascular permeability. The experiments with compound 48/80 lend further support to this view. Suppression of the early inflammatory changes in the skin and pleura by strophanthin G suggests that strophanthin G may be blocking the effect of local histamine release. It is thought that anti-histamines act by blocking the effects of histamine at tissue receptor sites, thereby preventing the normal physiological reactions to this substance<sup>8,9</sup>. The protective effects of antihistamines in preventing liver cell necrosis have been reported<sup>10,12</sup> to be due, in part, to their interaction with the system in the cell membrane which regulates active transport of sodium and potassium<sup>11</sup>. Both the antihistamine promethazine and strophanthin G have been reported to protect the rat liver against thioacetamide induced necrosis<sup>3,10</sup>. More recently, it has been reported that promethazine and strophanthin G show approximately equal activity in inhibiting potassium transport<sup>3</sup>. In the sheep the suppression by strophanthin G of the early inflammatory changes induced by histamine could be due to inhibition of the sodium/potassium ion transport mechanism of the capillary wall and this could, in return, suggest that part of the action of the antihistamine mepyramine maleate against histamine may be due to its action on the ion transport mechanism of the cell membrane.

Our results support the view put forward by Judah, Ahmed and McLean<sup>11</sup> that the antihistamines owe their

effects to their interaction with that system in the cell membrane which regulates the active transport of sodium and potassium ions. The results suggest that strophanthin G may prove useful in the investigation of the inflammatory reaction, particularly histamine liberation and the mechanism of exudate formation, in the sheep.

This work was supported by a Commonwealth fellowship and a university research grant to J. L. V.; and we thank Messrs. May and Baker for the supply of mepyramine maleate and Messrs. Burroughs Wellcome and Co., Ltd., for compound 48/80.

### Characteristic Pulse Wave caused by Organic Nitrates

NITROGLYCOL poisoning at dynamite factories has been a cause of concern for some time, but no specific and reliable diagnostic method for it has yet been established.

This communication reports a specific measurement of both nitroglycol and nitroglycerine poisoning. In a series of experiments, organic nitrates were given to human subjects and their effects on the pulse wave were examined by plethysmography. This method is suitable not only for detecting the degree of nitroglycol and nitroglycerine exposure before symptoms appear but also for measuring the degree of poisoning.

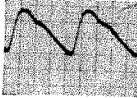

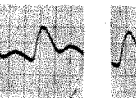

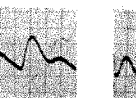

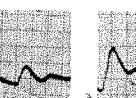

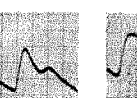

A variety of organic nitrates were administered sublingually as tablets, and nitroglycol was given as a 0.5 per cent aqueous solution, to healthy males aged 30–40 years. A reflexion photoelectric plethysmograph was used to record the condition of the blood stream in a finger. The recordings were made with the subjects lying on a bed. The most important index of toxicity is the contour of the pulse wave. This was characterized by a sharpening of the systolic curve of the pulse wave and by a depression of the diastolic notch, forming a distinct dent there. In addition to the pulse wave, the blood pressure and the electrocardiogram were measured at the same time.

The dose of the compounds administered varied from experiment to experiment, ranging from 0.5 to 8 mg for nitroglycol, 0.3 to 1.8 mg nitroglycerine, 10 to 20 mg for pentaerythritol tetranitrate, 4 to 6 mg for triethanolamine trinitrate diphosphate, 5 to 15 mg for isosorbide dinitrate, 10 to 20 mg for 2,2-dihydroxy-methyl-butanoltrinitrate, and 0.2 to 0.6 ml. for amylnitrite.

Before the experiments, all the subjects showed a similar pulse wave contour, designated as "normal" in Fig. 1. As the result of the administration of organic nitrates, the characteristic and similar altered pulse waves shown in the wave *BCD* of Fig. 1 were recorded irrespective of the variety of organic nitrate used. Fig. 1 shows these alterations of the pulse wave in a subject given 0, 0.9, 1.8 or 4.2 mg of nitroglycol sublingually; these contours of curve were classified as normal, slight, middle,

Table 1. PULSE WAVES, BLOOD PRESSURES, AND SUBJECTIVE SYMPTOMS AFTER NITROGLYCEROL ADMINISTRATION AND EFFECTS OF OXYGEN INHALATION

							
Time after initial administration of nitroglycerol (min)	0	2	5	7	11	16	30
Blood pressure (mm of mercury) (systolic/diastolic)	114/76		106/90	94/84	96/96	108/84	116/74
Symptoms	None	None	Slight headache	Slight headache	Chill, eye-lid spasm, dyspnoea	None	None

Administration of nitroglycerol: the initial dose was 0.5 mg, the second, third, and fourth doses were 0.5, 0.5, and 3.5 mg which were given 2, 3, and 7 min after the initial administration, respectively.

Oxygen was given 11 min after the initial administration of nitroglycerol.

and severe with reference to the pulse wave, pulse pressure and the symptoms shown.

The onset, duration and intensity can be assessed using this method by checking the change of pulse wave after administering organic nitrates. As shown in Fig. 1, wave B, a distinct change in the pulse wave was seen only 1 min after the sublingual administration of 0.9 mg nitroglycerol, while no subjective symptoms appeared. Table 1 shows the result of a typical experiment, in which a similar change occurred 2 min after administration of

0.5 mg nitroglycerol. In this experiment, three additional doses were given 2, 3 and 7 min after the initial dose. In addition to the typical changes seen in the pulse wave, a marked depression of systolic blood pressure occurred together with a moderate elevation of diastolic pressure. The fall in systolic blood pressure was so drastic that the pulse pressure dropped to zero 11 min after the first administration of the compound. Table 1 also shows the beneficial effect of inhaling oxygen: this gave a rapid restoration of blood pressure and eliminated the toxic symptoms.

To find whether organic nitrates can be absorbed through the skin, 1 g of dynamite was applied to the palm of one hand and changes in the pulse wave were checked on a finger tip of the other hand. There was no significant change in the pulse wave even after 30 min, but when the dynamite was applied and then covered by a surgical rubber glove the pulse wave began to show a characteristic change after about 5 min. The observation may indicate a possible absorption of vaporized nitroglycerol through the skin, although further experiments are needed if any unequivocal conclusion is to be reached.

The fact that the pulse wave is sensitive to organic nitrates was also confirmed during the examination of workers engaged in producing dynamite.

Various vasodilative and hypotensive agents such as 'Persantin', 'Segontin', 'Dyphyllin', benzylimidazoline, 'Hydergine', guanethidine sulphate, and hexamethonium chloride were examined in a similar way for comparison. These agents caused no changes in the pulse wave, but 50 ml. of whisky containing 40 per cent ethanol occasionally brought about a change which somewhat resembled that due to the organic nitrates.

In an additional experiment, the effect of asphyxia on the pulse wave was examined. As shown in Fig. 1, cessation of breathing for 1.5 min resulted in flattened pulse waves which were entirely different from those found with the organic nitrates.

This method might be considered too sensitive, but the contour of the pulse waves and the pulse pressure lead to a correct diagnosis of the condition of persons exposed to the toxic vapour which may be absorbed both by inhalation and through the skin. On the other hand, electrocardiograms seem to be of little use in this respect because they are not altered by administration of nitroglycerol and other organic nitrates.

Detailed reports on a field investigation at an explosive factory with reference to the use of protective gloves and the anti-anginal effect of organic nitrates will be published elsewhere.

I thank Mr. K. Muraki, Dr. Y. Ikoma, Mr. T. Tanaka and Professor M. Kuratsune for their help in this investigation.

## RADIOBIOLOGY

## "Division Probability" and Radiation-induced Cell Death

THE "non-surviving" members of an irradiated sample of cells frequently vary considerably in their mitotic behaviour—some fail to divide, others divide once, and abortive clones of various sizes are not infrequently produced. This heterogeneous response has usually been considered evidence that lethal damage induced by radiation is of several types. Whitmore and Till<sup>1</sup>, however, have suggested that "these different responses may be manifestations of the same type, and indeed even the same degree of damage". They have proposed a unifying concept of cell death termed division probability, which, if correct, would drastically alter the current interpretations of dose-survival curves.

Briefly, Whitmore and Till postulate that, *a*, radiation has the effect of reducing the probability that a cell will give rise to two viable offspring, and that, *b*, this reduced probability of successful division,  $p_2$ , is approximately the same for all cells of an irradiated sample and is maintained relatively unchanged through successive divisions after irradiation. In consequence, they would regard it as a matter of chance whether growth is terminated or proceeds indefinitely. Furthermore, if their theory is correct, the same type of damage would lead to termination of growth both before any cell division had occurred and after a varying number of progeny had been produced. This concept also provides a plausible explanation of the fact that colonies produced by "surviving" cells vary in size and rate of growth—the fraction of cells actually undergoing division at any one time would vary from colony to colony due to the operation of chance in preceding generations. Whitmore and Till have considered some of the implications of the presumed fixed division probability and have demonstrated its application by calculating values of  $p_2$  from experimental data.

It would be unfortunate if such calculated values were brought into general use before it had been shown that the mitotic behaviour of irradiated cells actually conforms to that expected from the concept. The necessary test is best carried out through straightforward observation of repeated cell divisions in an organism that is amenable to cell-pedigree analysis. One such organism is yeast.

Superficially, the response of yeast cells to irradiation agrees with that expected from the concept of a constant division probability in at least three respects. *a*, "Non-surviving" cells produce an array of abortive clones which contain from one to several hundred cells. *b*, Surviving cells produce colonies which are extremely variable in size and rate of growth. *c*, Clones produced by surviving cells frequently contain a mixture of dividing and non-dividing cells. Detailed studies of these three characteristics of radiation damage have been made by various investigators, and the degree to which they support or reject the concept is considered later.

(*a*) The frequency distribution of abortive clones does not always conform with that expected of the concept. An observed distribution of abortive clones ranging in size from one to thirty-two may be compared in Fig. 1 with the distributions expected of various  $p_2$  values.

Experimental results were obtained in the following manner: diploid cells of *Saccharomyces cerevisiae* were exposed to 40,000 r, an exposure which yields about 50 per cent survival in terms of counts of visible colonies on agar plates. Individual interdivisional cells were then isolated by micro-manipulator to the surface of solid medium. The relative frequency of abortive clones and the number of cells which each contained were determined by periodic examination throughout several days. For accurate counts, it was sometimes necessary to separate the cells of a clone. Expected values were calculated by computer, making use of the fact that after  $D$  generations

the relative frequencies of abortive clones containing exactly  $D$  non-dividing cells is fixed, and is

$$L(D)p_2^{D-1}(1-p_2)^D$$

where

$$L(0)=0, L(1)=1, L(2)=1, L(3)=2$$

and

$$L(D)=2L(D-1)+\sum_{j=2}^{D-2} L(j)L(D-j) \text{ for } D \geq 3$$

(T. D. Newton, personal communication.)

The greatest conflict between observation and expectation lies in the fact that the expected modal number of cells at termination of cell division is 1 for any value of  $p_2$ , whereas the actual modal number is 2. The fit would be improved by assuming that the unit of death is 2, that is, that death usually occurs, not before completion of division, but in both products of a division. This assumption is, however, unsatisfactory because it has been shown that the modal number does shift to 1 at higher doses<sup>2,3</sup>.

(*b*) Comprehensive studies of the temporary and of the hereditary consequences of irradiation indicate that the sizes and the rates of growth of yeast clones produced from irradiated cells are influenced by at least three factors regardless of the possible existence of a certain probability of non-division. (i) The size which a clone attains in a specified time is strongly affected by the temporary mitotic delay imposed by radiations in early divisions, and the extent of this delay is known to vary widely within samples of uniformly irradiated cells<sup>4</sup>. For the irradiated samples mentioned in this communication, the interval between exposure and the second division was found to vary between 2 and 24 h in instances where no other damage was apparent. The normal generation time was 2.25 h. (ii) Mitotic stimulation induced by irradiation also occurs in many cells after the second cell division<sup>5</sup>. This further increases colony variability because the extent of the stimulation is variable within a sample of cells and is only imperfectly correlated with the length of inhibition beforehand. (iii) Many surviving cells contain mutations which affect the rate of cell division<sup>6,7</sup>. Recessive lethal or near-lethal mutations, which depress growth rate on the average by 8 per cent,

Fig. 1. The frequency distribution of 306 abortive clones of *S. cerevisiae* which contained fewer than thirty-three cells, and the distributions expected from the operation of division probability with various values of  $p_2$ .

are induced with a frequency of about 20 per cent by exposures which give 46 per cent survival. Other mutations which reduce growth rate in the heterozygote occur with a frequency which is at least three times greater.

The effects of delayed death within clones produced by surviving cells are no doubt superimposed on the influences already mentioned. But it is clear that variation in clone size or growth rate cannot be used either as evidence of the existence of division probability or to calculate its parameters.

(c) Better evidence of the operation of division probability in yeast comes from pedigree analyses of surviving cells. The fact that irradiated cells produce clones which contain both dividing and non-dividing cells has been recognized for many years<sup>8-10</sup>. More recently, the phenomenon has been studied in detail<sup>11,12</sup>. In such studies, pedigrees are obtained by systematically separating the progeny of individual irradiated cells by means of a micromanipulator. This procedure reveals both the source and the pattern of production of non-dividing cells in mixed clones. Two pedigrees, which might be regarded as typical, are shown in Fig. 2. Such pedigrees are characteristic of more than half the survivors after exposures which give 50 per cent survival. Non-dividing cells appear throughout several generations as would be predicted by the theory, and the data emphasize a possible part played by chance in determining whether or not radiation damage is phenotypically expressed. Further, there is no doubt that radiation can produce a type of lethal damage in yeast which is not revealed by conventional plating procedures.

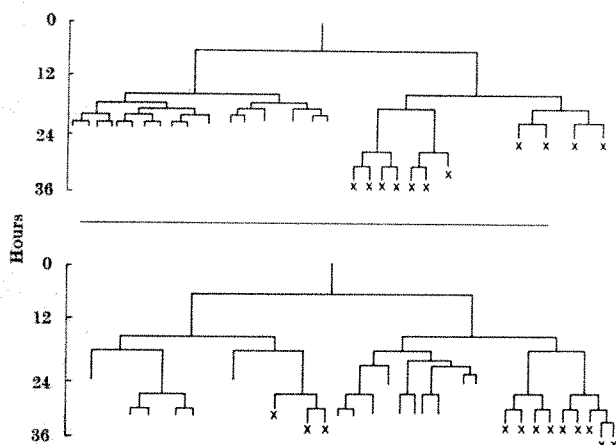

Fig. 2. Pedigrees of two X-irradiated cells of *Saccharomyces cerevisiae*. Each vertical line represents a separated cell, that on the left being the mother cell in any division. An 'X' denotes that no further division occurred. Otherwise, reproduction continued with eventual production of a visible colony.

Nevertheless, the pattern that has emerged with accumulating data is not that expected of the concept. *a*, Non-dividing cells usually appear in clusters rather than as isolated cells. *b*, The size of a cluster varies from one to more than 100 cells. *c*, These clusters appear as sectors and seem to be a consequence of residual growth after the initiation of some lethal event in an earlier generation. *d*, The risk that a cell will be the progenitor of a lethal sector decreases in successive generations. Nevertheless, instability has been noted after as many as eight generations. *e*, The degree of instability is not uniform for all cells of an irradiated sample.

These characteristics do not exclude the existence of a rapidly shifting probability of non-division, but they rule out a constancy in the value of  $p_2$  and in the number of generations between the occurrence of a lethal event and the termination of cell division. To be acceptable for yeast, the concept of division probability would have

to be altered so drastically as to lose the practical usefulness claimed for it.

### "Congenital Anomalies" induced by X-Ray

It was recently reported in your pages that prenatal X-irradiation produces a higher incidence of congenital anomalies in the offspring of primiparous mice than in those of multiparous mice, and that although the difference is not great, it is "indeed significant". In addition to gross external malformations, the classification "congenital anomaly" was also assigned by the writers to resorbed conceptuses, dead fetuses, and stunted survivors, although there is no justification for this practice, because these disparate phenomena may result from unlike effects of irradiation. Thus, collecting them together under one heading probably obscures rather than clarifies the nature of the damage done by prenatal irradiation.

I should like to go further and examine the authors' data<sup>1</sup>. When resorbed, dead and stunted offspring are omitted, it turns out that primiparous mice had 440 surviving young, of which 180 (40.9 per cent) were malformed; while the multiparae had 165/454 (36.3 per cent) malformed ones. This difference is indeed not great, but neither is it significant ( $\chi^2 = 1.78$ ,  $P \geq 0.2$ ).

It thus appears that the teratogenic susceptibility of the two groups of embryos was similar and that the previous reproductive history of the females was of no consequence.

## AGRICULTURE

### Effect of Environment on Wheat Gliadin

CHEMICAL and physical investigations have shown that gluten composition differs from one wheat variety to another<sup>1-5</sup>. The total protein as a percentage of the weight of grain of a particular variety is affected by environmental factors and may be twice as great in some samples as in others grown in different conditions. Variations of this kind within a variety can result in an alteration in the proportions of the broad protein classes<sup>6,7</sup> and could alter the distribution of components within classes. The work reported here was designed to test as rigorously as possible whether the second kind of change occurs within the gliadin class of proteins. It is desirable to know whether or not this type of change can occur if information on the composition of the gliadin is to be readily applicable to genetic investigations of inheritance of wheat quality.

The varieties of wheat used in this work and their ranges of protein contents were as follows: 'Gabo' (8.1 per cent to 17.9 per cent), 'Spica' (9.6 per cent to 16.0 per cent), 'Javelin' (8.9 per cent to 12.7 per cent), 'Quadrat' (8.3 per cent to 12.0 per cent). Thirty-three samples were obtained from six widely separated locations

Fig. 1. Starch-gel patterns of the acetic acid extracts of flour from four wheat varieties grown at two locations. Gels contained 14 per cent of hydrolysed starch and were prepared in 0.017 molar aluminium lactate buffer, pH 3.1, containing 2 molar urea. Period of running 5 h at 15 V/cm.

Fig. 2. Elution profiles of the proteins in soluble acetic acid of flours milled from 'Gabo' wheat grown in four different localities. Extracts containing 10 mg of nitrogen were applied to carboxymethyl cellulose columns (1.5 cm  $\times$  25 cm), equilibrated with 0.01 molar lactate buffer, pH 4.1, and maintained at 40° C. Protein was eluted by a 1,000 ml. linear salt gradient (0.02 molar sodium chloride) in the above buffer. Protein was estimated by the Lowry procedure.

Fig. 3. Elution profiles of extracts from four different wheat varieties grown at a single location, Narrabri. Experimental details as for Fig. 2.

(Merredin, Narrabri, Quandialla, Tamworth, Walpeup and Warwick) with a wide range of environmental conditions in four Australian states. The variety 'Gabo' was grown at all sites in two successive growing seasons, while at one (Merredin) the varieties were grown on two distinctly different soil types. Proteins soluble in acetic acid extracted<sup>8</sup> from flours milled from each of the samples were subjected to chromatography on carboxymethyl cellulose<sup>9</sup> and starch-gel electrophoresis<sup>10</sup>.

The results shown in Figs. 1-3 are typical of those obtained for the thirty-three samples examined. Starch-gel patterns for the four varieties grown in two of the locations are presented in Fig. 1. Fig. 2 compares the chromatographic profiles of the variety 'Gabo' grown in four different locations, and Fig. 3 illustrates chromatographic differences between varieties grown at a single location. It is clear that varietal differences are much more important than environmental factors in their effects on the starch-gel and chromatographic patterns (Figs. 1-3). The similarity between the electrophoretic and chromatographic patterns of the varieties 'Javelin' and 'Spica' was unexpected as they are not closely related genetically.

Variation between samples of the same variety (Figs. 1 and 2) may be a result of environmental factors, but it should be emphasized that these differences were small compared with the varietal differences and may be the result of experimental factors which are difficult to control. For example, apart from the inherent difficulties in reproducing exactly the chromatographic and electrophoretic techniques, the presence of variable amounts of other proteins, lipids and carbohydrates during extraction can result in the selective extraction of some gliadin components in preference to others.

The present investigation has not completely excluded the possibility of environmental effects on the gliadin composition of a variety, but it has demonstrated that the

combined effects of differences in locality, soil type, and season resulting in up to a two-fold variation in total protein content have little effect on the distribution of gliadin components. This suggests that the composition of gliadin could be a useful marker in work on wheat genetics.

We thank Dr. P. C. Williams of the Wagga Agricultural Research Institute for the wheat samples used in this investigation.

### Larval Phoresis of Chironomidae on Perlidae

A SPECIES of Chironomidae (Diptera) the larvae of which were living on the wing pads and legs of the immature stages of *Acronuria abnormis* (Newman, 1838) (Plecoptera, Perlidae) in streams around Ithaca, New York, has been reported<sup>1,2</sup>. Nothing has been added to our knowledge of this peculiar association since then. From May 1963 to January 1964 I observed what seems to be the same species in a stream near Wolf Lake, Pontiac County, Quebec. From larvae collected on their hosts, the other stages of metamorphosis have been reared and described as representative of a new species and a new genus of Orthoclaadini [sub-familia Orthoclaadiniinae], *Plecopteracoluthus downesi*<sup>3</sup>. The larvae fed on small particles, not on the Plecoptera themselves; thus the association is not parasitism, as had been suggested earlier, but rather it is phoresis.

The stream in which these larvae were found flows through two lakes which influence its temperature scale. During the summer months it has a moderate daily range, in spite of very different air temperatures by day and by night. The temperature of the stream, always measured in the early afternoon, was 12° C in May, 28.5° C in July, 8° C in October, and -0.5° C in late January (spot readings). In the faster regions the stream bed consists of rocks and big stones which are rather unstable, and there is almost no submerged vegetation. According to the classification of running water systems by Illies<sup>4</sup>, the region would be called the *hyporhithron*. The Plecoptera usually lived underneath the biggest stones, which were exposed to the strongest current. Of those that were carrying Chironomidae, 83 per cent were *Acronuria abnormis* (Newman, 1838), 6 per cent *Paragnetina media* (Walker, 1852), 5 per cent *Paragnetina immarginata* (Say, 1823), 3 per cent *Acronuria lycorias* (Newman, 1839), and 2 per cent *Togoperla media* (Walker, 1852), all belonging to the familia Perlidae. In early May 20 per cent to 40 per cent of the Perlidae were inhabited by *Plecopteracoluthus downesi*, and during the summer the percentage increased until in late autumn 82 per cent of all specimens of Perlidae collected were inhabited. From a sampling made on January 29, 1964, about 73 per cent of larvae of Plecoptera were found inhabited, and another 10 per cent were bearing cases but had lost the larvae themselves. Examining the host species separately it was found, in a sample of October 1963, that 96 per cent of all specimens of *Acronuria abnormis*, 45 per cent of *Paragnetina immarginata* and 37 per cent of *Paragnetina media* were inhabited, thus showing that *Acronuria abnormis* is the preferred host.

Of all the inhabited Perlidae that were examined, 50 per cent were bearing one older larvae and 10 per cent one younger larvae, while 40 per cent carried from two to four larvae each in various assortments of old and young. There are probably four larval stages, because four size classes could be identified in each sample that was taken, except in May when only the older larvae were noticed. The "younger larvae" probably represent the first and second, the "older larvae" the third and fourth, larval stages.

All larval stages live in gelatinous cases attached tightly to the body of larvae of Perlidae. The cases are often sparsely dotted with small dirt particles. They have a front and a rear opening, through either of which the larvae may emerge for about half their length when feeding. Most commonly (90 per cent), however, the larva lies head forward. The cases of the younger larvae are attached, almost always, between the hairs and bristles of the cerci or the metatibiae, more infrequently on the pro- or mesotibiae or at the surface of a wing sheath. The older larvae live almost exclusively on the surface of one of the wing sheaths, preferably that of the mesothorax. There was, however, no clear relation between the age of the larvae of Chironomidae and the age of host, except that most of the older larvae were on older hosts, probably because of their more convenient size. There seems to be no strict conformity in the life cycles of the members of this association. When rearing these insects in the laboratory, it has been observed that the larva will leave its case when the host larva is moulting and will move on to the newly emerging instar just as the old skin is being sloughed off. Thus, it can be assumed that the larva does not complete its development in the time needed for one instar of its host but can deal with the difficulties that may arise at the moults. On the other hand, the larval period probably has to be completed within the span of the aquatic (immature) stages of its host. On migrating to the new instar, the larva builds another case; and within such a case, eventually, pupation takes place. The pupa has not been found on free-living specimens and seems to last a very short time only, perhaps about 48 h. Before the imago emerges, the pupa leaves the case and swims to the water surface.

From the facts observed, it is clear that this association is not accidental but has ethological and ecological significance. There is little reason to call the association a symbiosis, for the host does not seem to derive any special benefit, other than the cleaning of its hairs, referred to below. The fact that the host species are carnivorous would be against the association and could indicate a danger when attachment is taking place. For the larvae of *Plecopteracoluthus downesi*, however, the association may have two advantages. The first one is in the obtaining of food. The contents of their guts showed that the larvae are detritus feeders but they are not adapted by structure or habit to filter such food from the water current, nor does their fast moving water habitat provide places where such fragments could accumulate. The larvae of Plecoptera, and above all *Acronuria abnormis*, possess dense and long fringes on the legs, cerci and some other parts, in which silt and organic particles accumulate. When keeping specimens of *P. downesi* on *Acronuria abnormis* in the laboratory, I could see the larvae stretching out from their cases, bending the front part of the body as though seeking for food, and picking up small pieces by the movement of their pseudopodes anteriores and mouthparts. This behaviour would be even more effective in the younger larvae, which live in the hair-fringes of the cerci or tibiae.

The second advantage may be that the small larvae of *P. downesi* are not able to cover great distances, as are their hosts. Thus, if a stone is displaced by the current, the hosts will more easily be able to avoid damage and to find a proper living site again than their inhabiting Chironomidae would be. This suggestion agrees with the hypothesis of Corbet<sup>5,6</sup> for the associations of *Simulium*.

with Odonata and Ephemeroptera; he considers that "the determining factor in the evolution of this association has been the need for *Simulium* in fast-flowing, unstable watercourses to secure a pupation site which gives protection against disorientation and damage". In the case treated here, however, it is not only the pupa that seems to benefit from the security guaranteed by the phoretic association but also, and perhaps even more, the larval stages; the larva, inside its case, is not only almost equally unable to move but much longer lived. There is also another factor which seems to be of strong selective value for the evolution of this association of Chironomidae and Perlidae. During the winter the larvae of *Plecoptera coluthus downesi* are almost immobile, while their hosts are still moving around. On January 29, 1964, the water temperature of the biotope was  $-0.5^{\circ}\text{C}$  and the host larvae were still active. The larvae of the Chironomidae inhabiting them did not move at all, however, and were apparently in a state of hibernation. In the laboratory, at a temperature still near freezing point, they did not react with the usual quick movement when touched with a needle. Even in water of about  $5^{\circ}\text{C}$ , it took about a quarter of an hour before they began to react. Thus, if larvae were dislodged during the winter they would not be able by themselves to avoid being damaged or swept away and would not be able to seek another shelter. All these problems are solved, however, when living in phoretic association with Perlidae. Thus, I consider that the one main factor in the evolution of the association of Chironomidae and Perlidae is the provision of accommodation for the larvae, which would otherwise be unable to endure the winter in perilous currents.

This work was carried out during my tenure of a post-doctoral fellowship from the National Research Council of Canada. I thank Mr. J. A. Downes and Dr. P. S. Corbet, of this Institute, for valuable suggestions and for reading the manuscript.

## PSYCHOLOGY

### Intracranial Self-stimulation in the Chick

In 1954 Olds and Milner<sup>1</sup> showed that rats would work to administer trains of electrical pulses through implanted electrodes to sites (for example, medial forebrain bundle, hypothalamus<sup>2</sup>) in their brains (self-stimulation). Self-stimulation has since been reported in the domestic cat<sup>3</sup>, rhesus monkey<sup>4</sup>, bottlenose dolphin<sup>5</sup> and domestic dog<sup>6</sup>. Euphoria has followed stimulation in the hypothalamus and tegmentum in man<sup>7</sup>. In vertebrates other than mammals, the only demonstration of self-stimulation appears to have been in goldfish (*Carassius auratus*)<sup>8</sup>.

In the present study very young domestic chicks were chosen for use because of recent demonstrations<sup>9</sup> of the relative permanence in the fowl of the effects of early learning on the choice of social or sexual partner ("imprinting"), or of food, which suggested that the neurophysiological basis of positive reinforcement would be of special interest in this species at this age. A second reason for the choice was the fact that positive reinforcers or conditioned stimuli for such reinforcement evoke vocalization<sup>9</sup>, thus providing a means of investigating the central effects of intracranial stimulation, independent of changes in the rate of the operant response which provides the stimulation.

The site chosen lay in the medial forebrain bundle, very slightly dorsal to the level of the anterior commissure. An insulated stainless steel electrode, exposed at its tip over the width of its cross-section (0.01 in.), was permanently implanted on the fourth day of life. Stimulation was applied between this and an electrode exposed for 3 mm of its length, which ran superficially in the forebrain, just under the skull. (Stimulation was applied between the tips of a bipolar electrode in *E1*.) Flexible leads, which were suspended from an overhead counterbalanced arm, and connected to contacts, which could rotate about a central bearing shaft, in circular mercury filled tracks, allowed free locomotion, including maintained circus movements. Pairs of square pulses of opposite polarity, 1 msec duration, and 0.2 m.amp peak to peak amplitude, were used in trains lasting 0.5 sec, at a rate of 100 pairs of pulses/sec, except where otherwise indicated. The current delivered to the brain was monitored on a 'Tektronix 5024' oscilloscope.

Male chicks (Warren sex-link) 18 h old were separated into isolation cages (8 in.  $\times$  8 in.  $\times$  14 in.) where they lived thereafter. When testing was about to begin (day 5, 6 or 8: Fig. 1), two identical keys were exposed in the wall of the cage, each consisting of a red sphere, 5 mm in diameter. (Two keys were presented to allow later experiments in which chicks chose between currents of differing duration or intensity.) If either key were pecked or pulled, it set in action a Grason-Stadler electronic clock, which timed the duration of stimulation, and a counter. A key operation produced exactly the same sequence of sounds from this equipment for a control (*C*) as for an experimental bird (*E*). All six experimental birds were run with a paired control from the same hatching, implanted at the same time, and with an exactly similar history. All controls were connected to overhead leads in the same way as the subjects during testing. *E4* on the first day and *C2* on the second day of testing served as yoked controls. Other controls received no stimulation.

All six experimental birds showed a marked increase of key operation, to an amount well above both their own previous rate of operation and that of their control, in the first 10 min after stimulation was made available (Fig. 1). (The duration of testing was not standard, because a session was not terminated until adequate recordings of vocalization during self-stimulation and protocols of associated behaviour had been obtained.) *E4* showed a slight but definite increase as a yoked control. The rise in rate of operation by *E4* on the second test day, however, when stimulation was made contingent on key

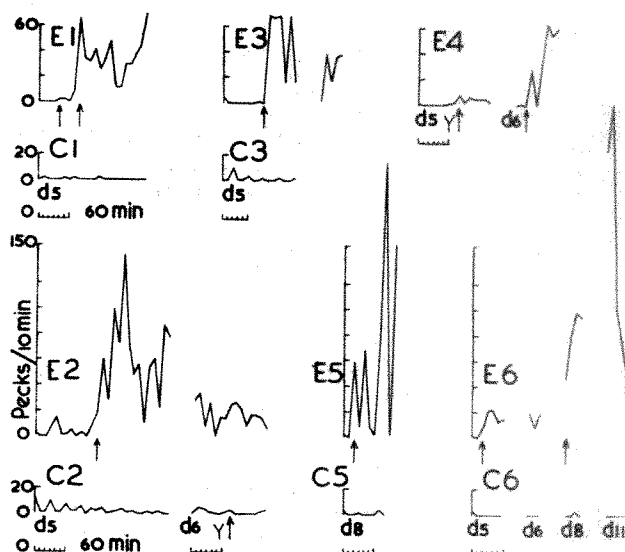

Fig. 1.

operation, was very much greater, and reached a level much above that reached by any control. This, and the fact that the other yoked control showed no increase at all after the onset of stimulation, indicates that the main effect of stimulation on the rate of operation in the subject is not caused by a general increase in activity.

The birds were killed on the fourteenth day of life, and their brains sectioned. All the subjects had correctly placed electrodes, but it was clear, as the tip of each track showed incipient healing over 0.5–1 mm, that the electrode tips had lifted during the last few days of life over this distance (within the medial forebrain bundle) from the original placement because of skull growth. This may explain the sudden and marked increase in rate on day 8 in the case of *E6*, rather than the lengthening of the train of pulses to 0.75 sec on that day. A seventh experimental bird, which never began to self-stimulate, was also the only *E* in which the electrode lay outside (and anterior to) the medial forebrain bundle.

The rates of stimulation, at their highest (260 pecks/10 min), are comparable with some reported maximal rates for equivalent areas in the rat (400 operations/10 min for the septal area<sup>9</sup>; 150/10 min for the medial forebrain bundle<sup>10</sup>). Moreover, the figures for the chick are not for highly trained animals, and are lowered by being averaged over 10 min because even the longest bouts of operation were not longer than 6–7 min and most were considerably shorter. Between bouts chicks slept and fed.

The fact that each peck resulted in a train of pulses, and that pecks were often given in rapid repetition, resulting in almost continuous stimulation while the pecks continued, makes it clear that all experimental birds would have worked for, and perhaps preferred, trains of considerably greater length (2–3 sec) than 0.5 sec, as is often true of the rat<sup>11</sup>. (This has been confirmed in later choice experiments, in which continuous stimulation was impossible. Trains of 0.1 sec would not maintain self-stimulation, and were consistently rejected in favour of 0.5 or 1.0 sec. Some chicks preferred 2.0 sec to 0.5 or 1.0 sec.)

The chicks gave, in association with self-stimulation, calls of a type also given to a variety of sources of stimulation which chicks tend to approach (for example, the imprinting object, food or signs announcing food<sup>8</sup>).

### Effect of Self-instruction on Perceptual Judgment

A MENTAL set, or "expectancy", may exercise a selective influence on the perception of ambiguous stimuli<sup>1</sup>. Such a set can be induced by a bodily need such as hunger, or by verbal instructions. The present study investigates whether an instruction which an individual gives to himself has more effect on subsequent perception than an instruction which he receives from an external source. There were three independent groups of subjects.

(1) In the self-instruction or reasoning group (RG), the subjects were presented with this conditional statement: "If the line on the left is longer than the line on the right, then the line on the right is red". A red line on their right

Table 1. FREQUENCY OF JUDGMENTS

	RG	IG	CG	
Longer	12	4	1	17
Equal	3	11	14	28
	15	15	15	45

was then exposed. The subjects were then asked what they could say about a concealed line on their left, and they all replied that it must be longer. They were then shown a red line of the same length on their left, and asked to judge its length relative to that of the previously exposed line. If they said it was longer, they were asked whether it actually looked longer.

(2) In the external instruction or information group (IG), the procedure was similar but instead of being invited to make an overt inference from a conditional statement, the subjects were told that the line on the left would be longer than the line on the right.

(3) In the control group (CG) the subjects were merely asked to judge the relative length of the two lines.

The two lines, strips of red 'Sellotape' fixed on white cardboard, were both 15 cm long and 0.5 cm wide. They were displayed on end in the same horizontal plane separated by 20 cm on a desk in front of the subject.

It was predicted that the frequency of perceptual judgments that the left line was longer would vary as follows: RG > IG > CG. A sample of forty-five subjects was selected at random from the student population of the University of London and assigned in rotation to the groups ( $n=15$  in each group). The subjects were tested individually and there was no time limit on any phase in the task.

Table 1 shows the number of subjects in each group who judged the left line as either longer than or equal to the right line. Three subjects, one in each group, judged it as shorter and were included in the equal category.

The prediction, RG > IG > CG, was confirmed with a high degree of significance (Kendall's  $S=330$ ,  $P=0.00005$ , one-tailed), but it will be noted that the difference between RG and IG is mainly responsible ( $P=0.005$ , one-tailed, Fisher's exact test), the difference between IG and CG being negligible. Eleven out of twelve subjects in RG, and three out of four in IG, who judged the left line longer, said it actually looked longer.

The results are consistent with Bruner's "hypothesis theory" of perception<sup>1</sup>, but they suggest that self-instruction is much more potent than external instruction. They are also consistent with the theory of "cognitive dissonance"<sup>2,3</sup>. The subjects in RG had committed themselves to an overt inference and might have been reluctant to contradict themselves in their perceptual judgments. The subjects in IG had not committed themselves—they were passive recipients of information. Their perceptual judgments would not have entailed self-contradiction; they would only have entailed contradicting the experimenter. Whether the results of this exploratory study were caused by perceptual or cognitive factors, they corroborate the notion that a belief, in which there is personal involvement, may distort our knowledge of reality.

It should finally be noted that all the subjects in RG were self-instructed from having made a logically invalid inference. Previous research<sup>4,5</sup> has shown that intelligent adults can be made peculiarly susceptible to this particular fallacy in a test situation.

I thank Miss Adele Kosviner, who conducted the experiment.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, February 27

INSTITUTE OF ACTUARIES (in Staple Inn Hall, High Holborn, London, W.C.1), at 5 p.m.—Prof. G. A. Barnard: "The Bayesian Controversy in Statistical Inference".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. B. M. Weedy and Mr. J. P. Perkins: "Steady-State Thermal Analysis of a 400 kV-Cable Through Joint"; Dr. B. M. Weedy: "Thermal Aspects of Changes in the Environment of Underground Cables".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. R. Pollard: "Storage Systems for Telephone Switching".

UNIVERSITY OF LONDON (in the Engineering Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. G. Kendall, F.R.S.: "The Arithmetic of the Kingman Semi-Group".\*

UNIVERSITY OF LONDON (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Charlotte Auerbach, F.R.S.: "Mutagenesis Research in Edinburgh. II, Mutagen Specificity".\*

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 6.15 p.m.—Dr. R. Gold and Mr. M. Paneth: "Management of Pulmonary Embolism".\*

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Meeting on "The Automotive Industry—Are Reinforced Plastics Making Progress?"

## Tuesday, February 28

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, S.W.1), at 4 p.m.—Dr. J. B. Rose: "Synthesis of Polyarylene Sulphones and Ketones".

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. H. W. Kropholler, Dr. D. J. Spikins and Mr. F. Whalley: "Control of Distillation Columns".

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. C. W. Kilmister: "What is Applied Mathematics and What Should It Be?" (Inaugural Lecture).\*

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Prof. J. R. Vane: "The Release and Assay of Hormones in the Circulation". (Fourteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

SOCIETY FOR ANALYTICAL CHEMISTRY, THIN-LAYER CHROMATOGRAPHY GROUP (at "The Feathers", Tudor Street, London, E.C.4), at 6 p.m.—Discussion on "The Use of Thin-Layer Chromatography for Identification Purposes" opened by Dr. A. S. Curry.

INSTITUTION OF THE RUBBER INDUSTRY, LONDON SECTION (at the Eccleston Hotel, Victoria, London, S.W.1), at 7 p.m.—Commercial Meeting.

## Wednesday, March 1

INSTITUTION OF ELECTRICAL ENGINEERS (joint colloquium with the I.E.E.E. and the Royal Television Society, at Savoy Place, London, W.C.2), at 9.30 a.m.—"Colour Cameras".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. R. A. French: "The Migration of Butterflies and Moths in Relation to Weather and Season" (Margary Lecture).

UNIVERSITY OF LONDON (at the Institute for Diseases of the Chest, Brompton Hospital, London, S.W.3), at 5 p.m.—Dr. M. Turner-Warwick: "Rheumatoid Factors in Lung Disease".\*

ROYAL SOCIETY OF MEDICINE, HISTORY OF MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5.15 p.m.—Sir Benjamin Rycroft: "The Evolution of the Corneal Graft".

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. H. V. Dunnington: "Stratigraphical Distribution of Oil Pools in the Iran-Iraq-Arabia Basin".

UNIVERSITY OF LONDON (at Senate House, London, W.C.1), at 5.30 p.m.—Sir Rudolph Peters: "Fluoride and Its Hazards in Nature".\*

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. H. R. Oakley: "The Disposal of Communal Waste".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Waltham Forest Technical College, Forest Road, London, E.17), at 6.30 p.m.—Mr. H. E. Barnett: "Measurements and the British Calibration Service".

## Thursday, March 2

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. C. M. Yonge, F.R.S.: "Living Corals".

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Prof. S. Rapoport (Berlin): "The Biochemistry of the Red Blood Cell". (Further lecture on March 6).\*

INSTITUTION OF CIVIL ENGINEERS, TRANSPORTATION ENGINEERING GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "The Influence of Transport Facilities on the Growth of S.E. England". Introduced by Major A. C. Dalgleish.

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Institution of Mechanical Engineers, at Savoy Place, London, W.C.2), at 5.30 p.m.—Meeting on "Control—a Unifying Force in Engineering Education".

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dr. G. L. Asherson: "Autoimmunity". (Last of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilation, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Mr. B. Lundvik (Stockholm): "Versatile Applications of the Screw Compressor".

## Friday, March 3

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 10.55 a.m.—Symposium on "The Experimental Taxonomy of Flowering Plants".

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W.1), at 1 p.m.—Dr. B. Stevens: "Photoaddition of Molecular Oxygen to Unsaturated Compounds".

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Annual General Meeting followed by Dr. A. A. Smales: "Our Society, Our Science—an Analysis" (retiring President's Address).

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. William Sargent: "The Mechanism of Brainwashing and Conversion".

## Monday, March 6

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. M. K. McPhun: "U.H.F. Tunnel-Diode Amplifier"; Dr. D. L. Hedderly, Mr. J. Hooper and Mr. M. K. McPhun: "Short-Hop Radio-Relay Systems Using Tunnel-Diode Repeaters".

UNIVERSITY COLLEGE LONDON (in the Chemistry Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. L. S. Bosanquet: "The Sum of an Unconvergent Series". (Inaugural Lecture).\*

UNIVERSITY OF LONDON (in the Main Lecture Theatre, Physics Building, Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. Sir Vincent Wigglesworth, F.R.S.: "Insect Hormones" (further lectures on March 7 and 8).\*

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. D. A. Dowden: "The Coherence of Pure and Applied Heterogeneous Catalysis".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. R. A. Hibbert: "Mongolia Today".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

RESEARCH ASSISTANT, SENIOR RESEARCH ASSISTANT or SENIOR DEMONSTRATOR (preferably with experience in electronics) in the DEPARTMENT OF APPLIED PHYSICS—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (March 4).

ASSISTANT LECTURER (with interests in mineralogy and petrology) in GEOLOGY—The Registrar, The University, Hull (March 10).

SENIOR ASSISTANT LIBRARIAN (with a degree and experience of dealing with scientific material, and preferably a professional qualification)—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey (March 10).

ASSISTANT LECTURER or LECTURER (with interests in any branch of pure mathematics) in the DEPARTMENT OF PURE MATHEMATICS—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 11).

RESEARCH FELLOW (graduate in mathematics, physics or electrical engineering) in the DEPARTMENT OF ELECTRICAL ENGINEERING, for studies in the synthesis of lumped linear electrical networks—The Registrar, The University, Leicester (March 11).

SCIENTIFIC OFFICER (with a good honours degree in zoology or applied entomology, preferably with postgraduate experience) to carry out laboratory and field studies on the behaviour and performance of insecticides in soil to improve their efficiency—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (March 11).

READER IN CLINICAL PHARMACOLOGY at St. Bartholomew's Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 13).

ASSISTANT LECTURER or LECTURER (preferably with interests and experience in any field of experimental psychology) in PSYCHOLOGY—The Secretary, University of Stirling, Stirling, Scotland (March 15).

LECTURER or ASSISTANT LECTURER (with a strong mathematical background and able to initiate a research group in mathematical logic, theory of probability or philosophy of mathematics) in PHILOSOPHY OF MATHEMATICS in the DEPARTMENT OF HISTORY AND PHILOSOPHY OF SCIENCE—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (March 15).

LECTURERS or ASSISTANT LECTURERS in the DEPARTMENT OF PHILOSOPHY, University of Singapore—The Inter-University Council, 33 Bedford Place, London, W.C.1 (March 15).

SENIOR LECTURER in the DEPARTMENT OF GEOGRAPHY—The Registrar, The University, Leicester (March 15).

SENIOR LECTURER in the DEPARTMENT OF PHILOSOPHY—The Registrar, The University, Leicester (March 15).

READER IN PHILOSOPHY at Birkbeck College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 16).

RAMSAY CHAIR OF CHEMISTRY (in the field of inorganic chemistry)—The Secretary of the University Court, The University, Glasgow (March 18).

ASSISTANT LECTURER (preferably with interests either in invertebrate physiology or in zooplankton) in MARINE BIOLOGY in the Marine Science Laboratories—The Registrar, University College of North Wales, Bangor, North Wales (March 20).

LECTURER IN STATISTICS in the DEPARTMENT OF APPLIED STATISTICS—The Registrar (Room 39, O.R.B.), The University, Reading (March 25).

LECTURER or ASSISTANT LECTURER (with research and teaching experience in chemical microbiology) in the DEPARTMENT OF BIOCHEMISTRY—The Assistant Registrar (S), P.O. Box 363, The University of Birmingham, Birmingham, 15 (March 31).

LECTURER or ASSISTANT LECTURER (with interests in the biochemistry of micro-organisms) in MICROBIAL BIOCHEMISTRY—The Registrar, University College of North Wales, Bangor, North Wales (April 10).

LECTURER or ASSISTANT LECTURER (with interests in the biophysical and biochemical aspects of soil-plant inter-relationships) in SOIL-PLANT NUTRITION—The Registrar, University College of North Wales, Bangor, North Wales (April 10).

LECTURERS or ASSISTANT LECTURERS (2) in the DEPARTMENT OF CHEMICAL ENGINEERING—The Assistant Registrar (Sci./Eng.), University of Birmingham, Birmingham 15 (April 14).

BIOCHEMIST (with an Hons. B.Sc. in biochemistry or chemistry) to join a team working on iron metabolism in liver disease—Dr. Roger Williams.

Clinical Research Wing, King's College Hospital, Denmark Hill, London, S.E.5.

**LECTURER** (with good qualifications in teaching and/or research and either interests and experience in some aspects of intermediary metabolism or in the applications of analytical techniques (e.g., gas chromatography) to biochemical problems) in **BIOCHEMISTRY** in the **BIOCHEMISTRY SECTION** of the **DEPARTMENT OF APPLIED MICROBIOLOGY AND BIOLOGY**—The Registrar, University of Strathclyde, George Street, Glasgow, C.1.

**MEDICAL DIRECTOR** (preferably registered practitioner with experience in drug evaluation and assessment) of the **National Drugs Advisory Board**—The Secretary, National Drugs Advisory Board, 6 Fitzwilliam Place, Dublin 2, Republic of Ireland.

**SENIOR LECTURER** (preferably with experience or interest in biochemistry or microbiology) in **BOTANY**—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

**SENIOR PHYSICIST** (with good academic qualifications and considerable experience together with an interest in modern methods of teaching)—The Headmaster, Clifton College, Bristol, 8.

## Mr. MACNAMARA and Mr. CROSLAND

It is ironical as well as sad that two of the most able men in the British and American governments should find themselves in a trans-Atlantic slanging match (see page 853) about technology and the brain drain. Mr. Macnamara, of course, has so far done no more than make a public speech which erred most seriously in being frank about issues which are usually ignored, but which was also well larded with the unavoidable complacency of those who can clearly see the solutions of problems which do not concern them directly. Mr. Crosland, rattled perhaps by three weeks of nagging about university fees for students from overseas (see page 853), and possibly wishing that there were more of the good red meat of politics in the administration of British education, was responding with the impatience of those who have learned by painful experience that it is easier to specify solutions to British problems than to attain them. And nobody, of course, will be surprised that both Mr. Macnamara and Mr. Crosland have right on their side.

It is, for example, splendid that Mr. Macnamara should have argued that the phenomenon which has become known as the technology gap is more a matter of management than of technology. If only enough people of his stature would say this more often, there would be less danger that technology will become a kind of magic wand for pretending that real problems do not exist. The most common form of this delusion is that which reads the link between technology and prosperity the wrong way round. Simply because the United States abounds with ambitious—and expensive—technological projects, and because the United States is prosperous, there is a perennial temptation for Europeans to believe that a few technological spectacles would make them prosperous too. Europe is littered with the relics of projects originally undertaken because of this magical belief. Mr. Macnamara has in particular done well to attack the notion that expenditure on defence technology is a sure way of creating prosperity. The frail doctrine of spin-off, or of technological fall-out as it is sometimes called, has nothing but optimism to support it—even in the United States. It is intellectually offensive because it implies that thoughtless effort is as productive as that which is consciously and conscientiously undertaken. If Mr. Macnamara can help to stamp it out from Europe, and keep it at bay in the United States, he will be a public hero.

Mr. Macnamara also dealt with a less obvious misconception of the value of technology—the tendency to regard it as advantageous in its own right, detached from its objectives. It is in this spirit that Signor Fanfani, the Prime Minister of Italy, started the

present excitement about the technology gap by raising the possibility of a kind of exchange of technology within the North Atlantic community as if technology were a kind of foodstuff to be shared out by some modern equivalent of the Marshall Plan. Mr. Harold Wilson, the British Prime Minister, has given support to this concept of technology as a kind of international commodity by commending British membership of the European Economic Community with the argument that Britain has a great technological dowry to bring to any marriage. But as Mr. Macnamara says, what counts is not skill but the capacity to use it. Modern techniques of management have their roots in technology, but they are also an attitude of mind. They are necessary, if not sufficient, conditions for closing whatever gap exists. Luckily, in Britain, the Ministry of Technology seems to have learnt this lesson, and may yet be able to educate the Prime Minister.

So why, then, was Mr. Crosland angry? The chances are that he would cheerfully accept Mr. Macnamara's homilies on the importance and the limitations of technology. Why then does he protest at the comparison on education? The trouble is that Mr. Macnamara's comment was too facile. It was not sensible of him to imply that if the nations of Europe wish to become more prosperous, they should make it their first responsibility to provide more education for more people for longer. In its way, this is as much of a fallacy as the belief that spectacular technology is the way to riches. Good systems engineer that he is, Mr. Macnamara should know that the problem is to maximize the economic benefit from the educational system, not the amount of education as such. In Britain, the problem happens to be exceedingly difficult because the traditions of selective and specialized education mean that the system can be at once inflexible, inequitable and sometimes superb. Mr. Crosland's problem is that the pace of change is limited not merely by the structure of the system but by the amount of effort and money that can be invested in it. The Swann report last year showed, for example, how the expansion of British universities in the past three years has used up a substantial number of people who would otherwise have found their way into industry—or possibly to the United States. The often intolerable frustration of the national disparities that Mr. Macnamara accurately identified is the constant awareness that desirable social amenities, such as a universal system of higher education, which are themselves sources of industrial strength, must be forgone for the sake of more compelling but less pleasing forms of investment. This is what Mr. Macnamara over-

looked. But he has done well to provide such an eloquent reminder that if the British feel badly about the comparison with the United States, less prosperous nations are likely to feel even more unhappy.

## RIBONUCLEASE

THE article by Dr. David Harker and his colleagues which appears on page 862 carries further the discussion of the tertiary molecular structure of ribonuclease. The fact that the team at Buffalo has been working on this problem has, of course, been common knowledge for some time. In spite of all the successes of the past few years, however, deriving the shape of a large protein molecule by X-ray analysis is still an exacting and a lengthy task. The difficulty is that an unambiguous identification of the positions of the atoms does require a sufficiently detailed analysis for individual atoms to show up on an electron density map. Sometimes, of course, a close similarity between two protein molecules may mean that information about one helps with understanding the other, but that does not often happen. This is why it was good to read in several newspapers in January that Dr. Harker's group had acquired a good head of confidence in their description of the ribonuclease molecule. At the same time, an article by Dr. C. H. Carlisle and his collaborators from Birkbeck College, London, was on the way into print in *Nature*. Now that both models have been published, it is plain that they differ from each other in several important ways. The fact that Dr. Harker's analysis implies a resolution of 2 Å, while Dr. Carlisle's is equivalent to 5.5 Å, will naturally make the American model seem the more convincing. One possibility, for example, is that Dr. Carlisle's model will come to seem more like Dr. Harker's as the analysis continues. Alternatively, further detailed study may suggest more radical changes to be necessary. These are not matters which can be decided lightly, but only by well-informed appraisal of whatever evidence may be available. It may be a great help that there is a third group, at Yale, working hard and quickly on the problem.

There remains the question of what these great endeavours are intended to accomplish. The fact that ribonuclease turns out to have the same general shape as the protein molecules the tertiary structure of which has already been determined, with hydrophobic groups inside and hydrophilic groups outside, is, of course, important if no longer surprising. But each new example of tertiary protein structure is bound to be a further help in the attempt to understand how tertiary structure is determined by the overall arrangement of amino-acids. The special interest of ribonuclease is that there is only one other enzyme molecule—lysozyme—the tertiary structure of which has been determined with accuracy and confidence. Obviously there will now be hopes that a comparison of the two enzyme molecules will provide clearer pointers

to an understanding of how enzyme molecules function than would be possible if there were just one model to work with. Unfortunately it is a long time since there were expectations that the sight of an accurate tertiary structure would indicate quite quickly the seat of its biological activity.

## WHAT NOW, APOLLO?

THIS is a critical time for the future of piloted space flights in the United States. Congress has at last begun picking over the budget of the National Aeronautics and Space Administration for the coming financial year. The process is more uncertain than usual because it is not yet clear how radically the space agency will be required to change its plans for the immediate future to prevent a recurrence of the kind of trouble which killed three astronauts on January 25. The signs are not, however, encouraging for the optimists. The third and most substantial report of the Board of Inquiry into the accident at Cape Kennedy, issued last week-end, has some ominous passages about complacency and miscalculation. Mr. James Webb, the chief executive officer of NASA, has openly acknowledged that the risk of fire was underestimated. It would not be surprising if Congress now took a cooler view of the urgency of sending men to the Moon than has previously been its custom. But healthy scepticism this year is likely to be particularly influential, if only because the foundations for the continuing programme of the NASA are going to be laid this year and the next.

What should a good committee man do? First of all, he is likely to ask how much the Apollo trouble is likely to affect the programme now mapped out by the White House for what is called the Apollo Applications Programme intended to occupy the early seventies. Briefly, the intention is to capitalize on the investment there has so far been in the family of Saturn rockets. In this scenario there are to be one or two flights each year by people to the Moon, and more frequent journeys by instruments to the planets. Optical telescopes in orbit about the Earth, with real astronomers in attendance, are included in the plans. But all this may now seem dangerously ambitious. Congress may choose to counsel caution. It would certainly be wise not to commit NASA to a specified level of expenditure without more information about the viability of the system for breathing oxygen in Apollo. Whether, in all this, the Air Force Project for a "Manned Orbiting Laboratory" will seem to be tarred with the same brush as Apollo because it has a similar oxygen system, or whether it will seem an attractive alternative, is not at this stage clear. And it is always possible, of course, that the Board of Inquiry will eventually have a hopeful tale to tell. But whatever happens, this is a valuable time for Congress to strike a blow for moderation in the exploration of space by people.

## NEWS AND VIEWS

### War of Attrition

MR. ANTHONY CROSLAND, Secretary of State for Education and Science, is unrepentant about his decision to raise university fees for overseas students. In a debate in the House of Commons on February 23, he defended his position with some skill, though he may have been rash to describe some Vice-Chancellors as "near hysterical". He also seems to be clutching at straws by quoting support from local authority associations; it would have been surprising indeed if they had supported the general increase in fees which Mr. Crosland offered as an alternative to the increases for overseas students, since any general increase in fees would fall most heavily on the local authorities. And if Mr. Crosland can find time to raise the matter informally and without commitment with the local authorities, people are bound to ask, as Mr. Nicholas Scott did in the House of Commons, why it was impossible to consult the Vice-Chancellors at all. Mr. Crosland was aided by a subdued Opposition, perhaps because some Conservatives felt their alliance with inflamed student opinion downright unnatural.

For all the fine words, universities have seemed slow to take action, beyond bombarding the minister and their M.P.s with telegrams. The University of Bradford, with 194 overseas students on its books, is prepared to remit fees to overseas students who are already at the university and can show evidence of hardship. Most of the other universities are waiting for a clarification of the position before they take any action. From Mr. Crosland's point of view, all that would seem necessary to forestall action would be to keep the arguments imprecise. Whether this is what happened at the meeting between the Vice-Chancellors and Mr. Crosland on February 28 is not clear, but in the circumstances the meeting could hardly be more than a trudge around well prepared positions. Another meeting will follow on March 7; so far time seems to have been spent in deciding exactly what an overseas student is, and how Mr. Crosland's hardship fund will work.

A lesson in good timing was supplied by the Fulbright Commission, which announced on the morning of the meeting a cut in the number of Fulbright Scholarships tenable both at American and at British universities. The decision, taken as a direct result of the increase in fees, is intended to share the extra cost between British and American scholars. Instead of 211 British postgraduates going to American universities in 1967-68, there will be 194. Similar steps may also be expected from Europe, where there are more British students than there are European students in British universities. In the European Economic Community it is the policy to encourage the movement of students even during undergraduate courses. Britain, as a candidate for Common Market entry, will not seem to have behaved diplomatically.

The fury caused by Mr. Crosland, of course, does not consist wholly of moral righteousness; the Vice-Chancellors, after all, favour a general increase in

student fees. Face to face with the Department of Education and Science, the universities have found that much of their freedom is a polite fiction, preserved by the University Grants Committee. What is surprising is that this should have come as such a shock to them.

### What Macnamara said

THE view that what is called the technological gap between the United States and Europe is more a matter of management than technology was one of the themes in a speech by Mr. Robert Macnamara, United States Secretary of Defence, at Millsaps College, Jackson, Mississippi, on February 24. Newspaper reports of Mr. Macnamara's diagnosis of the reasons why scientists leave for the United States provoked an angry reply last week-end from Mr. Anthony Crosland, Secretary of State for Education and Science in the United Kingdom.

On the disparity between the United States and Europe, Mr. Macnamara said that "it is not so much a technological gap as a managerial gap . . . The brain drain occurs not merely because we have a more advanced technology here in the United States, but rather because we have more modern and effective management. God is clearly democratic. He distributes brain-power universally. But he quite justifiably expects us to do something efficient and constructive with that priceless gift. That is what management is all about—it is the gate through which social, political, economic, technological change—indeed change in every dimension—is rationally and effectively spread through society . . ."

Mr. Macnamara went on to say that Europe could not close the gap by boycotting American technology, by high tariffs, or by prohibiting investment. Restricting emigration would not help either. There was no future in the establishment of a defence industry "on the dubious economic theory that only through massive military research and development can a nation industrialize with maximum speed and benefit". In the long run, Mr. Macnamara said, only education could help. "Europe is weak educationally and that weakness is seriously crippling its growth. It is weak in its general education; it is weak in its technical education; and it is particularly weak in its managerial education".

He went on to say that in the United Kingdom, France, Germany and Italy, fewer than 20 per cent of schoolchildren remain at school after 15, but that 45 per cent of American children were still at school at 18. In the United Kingdom, he said, "there are some 336,000 students enrolled at university level. Only 10 per cent of college age people stayed on for higher education, with seven per cent in Germany, seven per cent in Italy, and fourteen per cent in France. But in the United States, said Mr. Macnamara, there were four million college students, amounting to 40 per cent of the population of college age.

What seems to have irritated Mr. Crosland most is the suggestion that the uniform distribution of brain-power is all that matters. "One thing that God does not distribute equally is wealth." He said that the reason that "brains move from every country of the world to America is that America . . . is the richest country in the world and can pay much for brains". The brain drain, he said, was now a serious matter of

conscience for the richer countries, particularly the United States.

## Aircraft for Aldabra?

THE Council of the Royal Society has taken the unusual step of making public its "considerable concern" about the future of Aldabra Island, in the Indian Ocean north of Madagascar. The immediate anxiety is that the British defence authorities are interested in the island as a possible air staging post in the Indian Ocean. In a statement published last week the council of the Royal Society says that Aldabra is the only island in the Indian Ocean which has remained "essentially unaffected by man", with the result that its flora and fauna contain many species not found elsewhere. Indeed, the island supports something like 10,000 of the land tortoise (*Testudo gigantea*) which is now found in its natural state only on Aldabra and the Galapagos Islands. Among the notable sea-birds are frigates (*Fregata minor* and *Fregata ariel iredalei*) which are likely to be a hazard to aircraft if an airstrip is ever built. The land birds include a flightless rail (*Dryolimnas cuvieri*). Although frigate birds occur elsewhere in the Indian Ocean, Aldabra is the principal breeding ground for them as for the green turtle (*Chelonia mydas*) and the hawksbill turtle (*Eretmochelys imbricata*). It is also estimated that 10 per cent of the 170 plant species on the island do not grow elsewhere. There is little doubt that Aldabra is an isolated island ecosystem of unparalleled interest.

The interest of the Ministry of Defence stems from the recognition in the early sixties that a continued British presence East of Suez would require air staging posts in the Indian Ocean. The map of the Indian Ocean suggests that Aldabra Island would be valuable if Aden were untenable by the Royal Air Force. The Ministry of Defence says that other islands in the neighbourhood have been considered as staging posts, and says that it has promised the council of the Royal Society that the "scientific case for the preservation of Aldabra will be fully considered before a decision is made". The Ministry also says that if it should decide to make a staging post at Aldabra, it will do everything it can to protect the species living there, and that even though the frigate birds would be a hazard, there is no question of exterminating them. The trouble with this kind of assurance, of course, is that the experience of the nineteenth century, when the atolls of the Indian Ocean were widely exploited for their guano, coconuts and turtles, shows how little outside interference is necessary to disturb the balance of the ecosystem.

Aldabra is by all accounts an inhospitable place, which accounts for its isolation. At present the island supports a population of 80 to 100 migrant workers from the Seychelles. One of the particularly objectionable features of the proposal to build an airstrip is that this would have to be sited on the part of the atoll ring at present separated from the human settlement and which is also frequented by the land tortoises. Although the fact that the Royal Society has chosen to make its anxiety public is a sign that it is afraid of reading in the newspapers one day that Aldabra is to be an airstrip, relations with the Ministry of Defence are friendly enough for the Royal Navy

to have agreed to ferry to the island in August this year the two scientists whose reports in 1966 drew attention to the dangers that an airfield would bring. It is now planned that a scientist should remain on the island at least until Easter 1968.

## Research into Environment

THE Centre for Environmental Studies has now been formally established as an independent charitable trust for advancing education and research in the planning and design of the physical environment. Announcing this in a written answer in the House of Commons on February 21, Minister of Housing and Local Government Mr. Anthony Greenwood, said that the Ford Foundation had given \$750,000 to the centre and, if Parliament approved, the Government intended to give a grant of one and a half times this amount for the first five years, up to a maximum of £600,000. Eight members of the ten strong governing body had already been appointed; the Chairman would be Lord Llewelyn-Davies, and the Vice-Chairman Sir William Fiske. One international governor had been appointed in consultation with the Ford Foundation—Mr. M. Meyerson—and others who had accepted appointments as governors were Mr. C. D. Foster, Lord Helford, Lord Jellicoe, Mr. W. Taylor and Professor R. M. Titmuss. Dr. A. H. Chilver had been appointed Director of the Centre from April 1, 1967.

Lord Llewelyn-Davies said this week that the centre, based initially on London, would have three functions: discovering (by discussions and conferences) the areas in which research is needed, sponsoring research in universities, and interesting itself in information retrieval and dissemination. As well as architectural planning, it would hope to support research in economics, sociology and geography. There had, he said, been pressure to recognize this area of research, and the new centre was the result.

## University of Cranfield?

THERE may be an educational precedent of some importance in the way in which the College of Aeronautics at Cranfield has applied to the Privy Council for a charter that would allow it to award its own higher degrees in engineering subjects. Discussions between the college and the Department of Education and Science have been going on ever since the Robbins Report recommended, in October 1963, that the college should be brought within the university system. At present the college is a direct pensioner of the Department of Education and Science. Inquiries at the University Grants Committee and the Department of Education and Science suggest that it is not yet clear whether the granting of a charter will mean that the college is financed like the universities, through the University Grants Committee, or like the polytechnics, through the Department of Education and Science. It does, however, seem that the college has successfully resisted suggestions that it should accommodate itself under the wing of an existing university or, alternatively, that it should make use of the degrees being awarded by the National Council on Academic Awards. The way in which the college has been pointing out that it lies a mere three miles from the site of the proposed city of Milton Keynes may indicate that

it has great ambitions for the future. Indeed, the college is hoping that its student population of 350 or so—all of them postgraduates—will increase to about 1,000 in the seventies.

## Asbestos in the Lungs

THERE are at present 250 registered cases in Britain of mesothelioma, the cancer tumour associated with asbestos dust contamination. A tumour of the lung lining (and occasionally the peritoneum), it can reach remarkable dimensions, is terminal and has not so far been known to develop without a relationship (however remote) with dust from asbestos of the crocidolite type—blue asbestos.

Four fibrous silicates with the generic name asbestos are in commercial use. These are: crocidolite (blue); amosite (brown); anthrophyllite (white); and chrysotile (also white) which is by far the commonest. Asbestos is in increasing demand for many industrial uses, especially in shipyards and for pipe-lagging. The material must be mined, milled and fabricated and at each of these stages a fine penetrating dust is produced, but this is not the full story. So far, only the dust from blue asbestos has been definitely implicated as carcinogenic. The relationship was established in the 1950s in South Africa, where the principal blue asbestos mine is located. It was found that on average the disease takes 40 years to develop, but that fatal exposure could be as short as three months in childhood. More than half the cases investigated had not worked in the asbestos industry but had been open to environmental exposure only. It is disturbing that these cases arose from exposure in the early days of the Cape industry—it started in 1890—when annual crocidolite production was only 10,000 tons. Now more than 80,000 tons a year are produced, and much of this milled for short fibres.

To define the relative hazards, a world-wide survey is being organized by the International Union against Cancer (UICC), with the active participation of the MRC Pneumoconiosis Unit at Penarth, Glamorgan-shire, where one of the South African researchers, Dr. J. C. Wagner, is now working. To help in comparable laboratory experiments, an international asbestos dust bank of standard samples of the economically important asbestos types has been established. For the epidemiological research it is necessary to go to the asbestos mining countries to look at the communities exposed to only one type of asbestos fibre. Surveys are already in hand in South Africa (crocidolite, chrysotile, amosite), Finland (anthrophyllite) and Canada (chrysotile), and it is hoped that the other chrysotile producers, the Soviet Union and Cyprus, will soon join in.

Follow-up studies of industrial populations where a single type of asbestos has been used are also valuable. In Germany crocidolite was extensively used in the construction of the First World War Grand Fleet. 4,000 people worked in a crocidolite factory in London, in the early 1900s, and Californian shipyards where amosite was employed in World War II. British follow-up studies have been greatly hampered by the eccentric mode of national record keeping. It has taken four years to trace 98 per cent of the men from the London factory, and many of the women employed have escaped the net completely because records lose track of

them at marriage. The Director of the Unit at Penarth is severe on the subject: "In this country we don't make use of modern methods in either record-keeping or retrieval" and compared the situation unfavourably with the United States and Finland—Finland in particular provides "magnificent death certificates". "At present, the Ministry of Health is not interested in occupational disease," he said.

## Pugwash in Australia

DR. PATRICIA LINDOP writes: The first South-east Asian Regional Pugwash Conference was held in Melbourne from January 23–27, when scientists from Australia and New Zealand, Japan, Indonesia, Malaysia and Ceylon, India, Pakistan and Singapore discussed the application of science, technology and industry to the development of the region. The conference was yet another experiment and step forward in the evolution of the Pugwash Movement.

During the past ten years, the chief Pugwash activity has been in international conferences discussing, particularly in an East–West context, problems arising from development of weapons of mass destruction, and ways towards reducing the likelihood of their use, by disarmament. Some attention has also been given to the other potential source of international tension—the increasing disparity between the developed and developing nations. It was felt that to tackle this problem effectively, and within the available resources of time and money, it was necessary to deal with some of the problems on a regional basis. The need to discuss regional development as well as South-east Asian security made the initiative of the Australian scientists in organizing this first meeting most timely. Unfortunately, but perhaps understandably, the Chinese scientists did not come to Australia, although it is hoped that they will be interested in future regional meetings.

The meeting itself set one again wondering what exactly is Pugwash and its effectiveness? Each individual scientist probably looks for or finds something different in Pugwash, and the only common factor is in the desire to prevent the misuse of science. But the Pugwash-type discussion is quite different from other more formal international conferences on the same or similar topics. For example, in Melbourne there was no real discussion of "aid" to neighbouring countries—only of the necessity for co-operative action and mutual education and development. There was objective and constructive criticism of the mechanisms of the existing aid schemes from both donor and recipient countries. A need in all countries was for a scientific committee to vet and co-ordinate co-operative projects in science and technology, and to ensure the better use of scientists and equipment. At present, even in a donor country such as Australia, scientific consultation is on an informal and piecemeal basis. In countries of the region where the scientific cadre is at present too small to have much influence in government planning, the support of scientists from other countries in the region in providing an objective assessment of projects was greatly welcomed. And during the few days of the meeting the atmosphere changed from one of helplessness to a realization that the problems were the same in all other countries in the region, whether economically more or less

developed; and that a co-operative approach with good international communication and consultation in the region could be most effective.

## Cow Green Lost

THE battle for Cow Green was finally lost in the House of Lords on February 23, when the Tees Valley and Cleveland Water Bill was given its third reading. This ended what Lord Grenfell described as an exhaustive and somewhat exhausting inquiry into the Bill sponsored by the Water Board and Imperial Chemical Industries, Ltd., seeking to build a reservoir in Upper Teesdale (*Nature*, 212, 442, 656, and 764; 1966). The committee set up to defend Cow Green, while regretting that it has lost the battle, believes that people are now more aware of the danger to amenity and to botany which schemes of this sort represent. The Defence Committee will now disband, but a wary eye will be kept on developments by a joint working party from the Council for Nature and the Council for the Preservation of Rural England. This group is particularly concerned with water resources, and apart from reporting back to its parent bodies it may also publish its findings from time to time.

## Navigation on Show

UNDER the unsuitably melodramatic title of "Man is not Lost" the National Maritime Museum has launched an exhibition to celebrate the bicentenary of the first issue of the Nautical Almanac and Astronomical Ephemerides for 1767. These tables enabled seamen to determine their position at sea accurately by measuring the angular distance of the Moon from certain fixed stars, and until Harrison's chronometer came into widespread use in the 1830s it was the only satisfactory method of determining longitude. Although vitally important in the history of navigation, the Nautical Almanac is not the most interesting subject on which to base an exhibition, and the organizers are to be complimented on the way they have tackled the problem. Choosing to stress the historical importance of the Almanac they have set the exhibition out under the following headings: the founding of the Royal Observatory of Greenwich in 1675; the compilation of the Nautical Almanac by Maskelyne in 1765 and its publication in 1767; the development of the method of position lines for determining latitude and longitude in the mid-nineteenth century; modern methods, which began to be used in 1914, and which included the applications to air navigation in 1937; and astronomical navigation today. The exhibits are all intelligible and well presented, if sometimes incompletely supported by information. The outstanding exhibit is a model which the visitor can operate to measure lunar distances in the same way as they were measured in the past.

## Floral Stamps

IN its choice of designs for the latest set of eight special postage stamps depicting the British flora (on sale on April 24) the Post Office has reached a compromise between the demands of minuscule design and those of botany. The Rev. W. Keble Martin, whose designs for

the new 4d. stamps were selected, is a keen amateur botanist who has been drawing flowers for sixty years. Mary Grierson, who designed the 9d. and 1s. 9d. stamps, is the official artist at the Royal Botanic Gardens, Kew.

The artists were asked to submit designs showing familiar members of the British flora. Their final choice was dictated by the need to depict flowers which would be clearly visible against a white background when reduced to the size of a postage stamp. The results are perhaps not every ecologist's dream of a representative selection of the British flora, but hedgerows, woods, fields and waste places—all common British habitats—are well represented, if rather sedately, by twelve familiar flowers. The stamps show flowers rather than whole plants, for extraneous leaves and stems have been eliminated, and this also applies to the names of the plants, omitted for reasons of design and to avoid taxonomic repercussions.

## Molecular Weights without Tears

by a Correspondent in Molecular Biology

THE development of photoelectric absorption optics for the analytical ultracentrifuge has for the fortunate possessor of such equipment remarkably simplified the problems of molecular weight determination, and makes it possible to perform accurate measurements on unprecedentedly small (microgram) quantities of proteins and other substances. In this system, the ultracentrifuge in effect incorporates a double-beam spectrophotometer, the sample and reference (solvent) being placed in the two compartments of a double-sector centrifuge cell. By scanning the contents of the cell at a wavelength at which the solute absorbs light, the complete concentration distribution can be obtained. At sedimentation equilibrium this leads at once to a molecular weight; the tedious routine of a separate concentration run (which is required by other optical systems that measure only concentration gradients) and dialysis of the solution against solvent are obviated. Moreover, unless the extinction coefficient of the solute is low, the concentration required for the measurements is so small that no extrapolation to infinite dilution is needed, and a single experiment suffices for the determination. This and other benefits accruing from the use of this technique, such as possibilities for the study of ligand binding, have been explored by Schachman and his associates.

In the latest paper in this series, Edelstein and Schachman (*J. Biol. Chem.*, 242, 306; 1967) now describe

how a single experiment with photoelectric absorption optics can yield both partial specific volume and molecular weight. The former quantity is required for all ultracentrifugal molecular weight procedures. Its independent measurement requires a substantial amount of material, and solutions of precisely known dry-weight concentration. For proteins, a moderately reliable value can be calculated if the amino-acid composition is known and if there are no prosthetic groups; in many cases, however, and especially perhaps for nucleic acids, the partial specific volume is arguably the limiting factor in molecular weight determinations.

Edelstein and Schachman measure in a single experiment the sedimentation equilibrium distribution in  $H_2O$  and  $D_2O$  solutions of identical concentration in separate cells. They show that a correction, which is effectively the same for all proteins, can be applied to account for the small change in molecular weight resulting from hydrogen-deuterium exchange. From the standard equilibrium plots ( $\ln c$  against  $r^2$ ) for the two solutions, the partial specific volume is easily derived, and an accuracy of 1 per cent is reported. The precision of the method can be further enhanced if  $D_2^{18}O$  is available as a solvent; for a typical protein the slope of the equilibrium plot is then nearly halved compared with  $H_2O$  solution. Values of the partial specific volume and molecular weight obtained by these procedures for adenosine and a range of proteins are in remarkable agreement with accepted data. Edelstein and Schachman point out that their method can be applied even in the presence of other sedimenting species if the substance under study happens to have an absorption band in a separate region.

In referring to the work of Simon and Konigsberg (*Proc. Nat. Acad. Sci., U.S.*, **56**, 749; 1966) in this column on December 10, 1966, their conclusions were incorrectly represented. Whereas the first report by these authors (*Fed. Proc.*, **25**, 648; 1966) stated that cross-linked haemoglobins had been prepared which were incapable of dissociating into sub-units, the later article instead reports intramolecular cross-linking, and no bonds between sub-units. The annihilation of the haem-haem interactions evidently results therefore from the chemical disturbance of the  $\beta$ -chains as such and not from inhibition of sub-unit exchange.

## Survival of Starved Bacteria

by a Correspondent in Microbiology

ORGANISMS might be expected to respond to adverse environments by a suspension of synthetic activities so as to become more independent of their surroundings but, in practice, bacteria rarely respond in this way. The synthesis of cell components may continue, possibly at altered rates, during prolonged starvation. Continued synthesis under starvation conditions leads to aberrant protoplasm which may ultimately prove lethal. In the current number of the *Journal of Bacteriology* are published a series of papers by Kennell, Kotoulas and Marchesi (*J. Bact.*, **93**(1), 334, 345 and 357; 1967) which discuss various aspects of nucleic acid and protein metabolism in starved *Aerobacter aerogenes* cultures. Starvation conditions were established by harvesting exponentially growing cells and

resuspending them in the growth medium lacking magnesium. Although natural environments are probably rarely or never deficient in  $Mg^{++}$ , this starvation system was studied because on present evidence magnesium is the most frequent metal co-factor for metallo-enzymes and is intimately concerned with ribosome stability.

In the  $Mg^{++}$  deficient medium, *A. aerogenes* continued synthesizing nucleic acids and proteins for more than 70 hours provided that the source of carbon was not limiting. During the initial 24 hour period, the DNA content of the culture increased ten-fold, but the viable count showed only a three-fold increment during the first few hours and thereafter remained approximately constant. The ribosome population became "frozen" when the cells were incubated in the starvation medium. This constancy was maintained by the rate of ribosome degradation (induced by  $Mg^{++}$  deficiency) being paralleled by an equivalent rate of synthesis. Ribosome degradation was sequentially ordered and particles derived from degradation did not appear to be exchangeable with those in the process of assembly. Ribosomal proteins which had been synthesized during the preceding phase of growth in the complete medium were lost steadily during starvation and accounted for the total protein loss from the starving cells. Magnesium starvation of uracil-requiring strains of *A. aerogenes* produced confirmatory results: during uracil starvation a smaller fraction of the synthesized proteins were ribosomal and the amount of protein which decayed during the subsequent  $Mg^{++}$  starvation was proportionally reduced.

Cytochemical changes accompanying  $Mg^{++}$  starvation are also described by these authors (*J. Bact.*, **93**(1), 367; 1967). A progressive decrease in cell size occurred during the initial period when an expanding viable population was paralleling DNA synthesis. However, the subsequent phase of continued DNA synthesis and constant viable population showed cells becoming elongated into filamentous morphologies and, in addition, a second population of very small cells appeared. The latter, probably the result of disparate cell division, comprised an increasing proportion of the total population but (i) were unable to grow or divide when returned to complete media, and (ii) were devoid of biosynthetic activity as assessed by uracil- $H^3$  incorporation into nucleic acids. Furthermore, these cells appeared almost completely lacking in ribosomes. After 20 hours of starvation, the very small cells accounted for more than 80 per cent of the population and were enough to explain the disparity between the total DNA content and the viable complement of the starved culture.

A continuation of normal cell division throughout starvation would lead to a diluting out of the ribosomes in the population so that the number per cell would be insufficient to maintain the metabolic potential and viability of the population. Kennell and his colleagues conclude that the very small cells arising from this apparently inevitable division activity are sacrificed in order to preserve a line of viable cells—the filamentous cells. The regulation of such a differential survival mechanism is an intriguing problem and it remains to be seen whether this type of differentiation is general in starving bacteria under different starvation conditions.

## Parliament in Britain

MR. R. MAUDLING, in opening a debate in the House of Commons on February 23 about the proposed increase in fees for overseas students, once again questioned the magnitude of the anticipated savings of £2.5 million per year. The Secretary of State for Education and Science, Mr. A. Crosland, who followed, gave figures as to the increase in the subsidy to overseas students over the last 10 years. He stated that over 95 per cent of the fees of undergraduates were paid out of local authority awards, and claimed that to increase the fees of all British university students to the point where they represented 20 per cent of recurrent costs as proposed by the Robbins Committee and the Estimates Committee would involve an addition of £8 million to the rates. There was a consensus of opinion that the number of overseas students should be maintained at least at its present level, and in winding up for the Government, Mr. G. Roberts could only add that what had been said would be carefully considered and that the total grant to universities could assume an increase of £250 per annum per overseas student.

In reply to questions in the House of Commons later in the week, Mr. A. Crosland gave an analysis of the geographical origin of the 16,256 full-time overseas students at British universities in 1965-66: 1,873 were from Western Europe, 9,081 from the Commonwealth, 1,643 from the United States and 3,659 from other countries. Of those from Commonwealth countries, 1,289 were estimated as from advanced and 7,792 from developing countries. Of the 16,256, 2,189 were supported by United Kingdom public funds; 970 from other United Kingdom funds, including University awards; 2,415 by the Governments of developing countries; 1,906 by other overseas governments and services; and 8,776 were privately financed. In all 10,890 came from developing countries and 5,416 were privately financed. No figures are available of overseas students who hold no awards but 4,855 from Commonwealth countries were privately financed.

In a written answer in the House of Commons on February 13, the Minister of State, Mr. G. Roberts, gave the expenditure of the Medical Research Council in 1963-64, excluding capital expenditure, specifically on cancer research as £958,000, of which £531,000 was on the Council's units and external staff, £373,000 on grants to university research workers and £54,000 on grants to other research workers; for 1964-65 the corresponding figures were £1,029,000, £548,000, £415,000 and £66,000; for 1965-66, £1,178,000, £643,000, £461,000 and £74,000; and for 1966-67, £1,270,000, £696,000, £484,000 and £90,000. No estimate could be given of the proportion of Government funds applied to this purpose from grants given on the advice of the University Grants Committee to universities and medical schools or of the amount spent by hospitals within the National Health Service.

BARONESS PHILLIPS, answering a question in the House of Lords, said that in 1965-66 there were 2,471 undergraduate students of agriculture and 562 post-graduates in British universities. Rationalizing the teaching of agriculture in Britain was the responsibility of the U.G.C., she added.

## University News:

### Aston in Birmingham

DR. E. BRAUN, at present head of the Department of Physics in the West Ham College of Technology, has been appointed professor of physics as from September 1.

### Birmingham

THE personal title of professor of comparative endocrinology has been conferred on Sir Francis Knowles, reader in comparative endocrinology at the university.

### Cambridge

DR. P. W. ANDERSON of the Bell Telephone Laboratories will be visiting professor in theoretical physics at the Cavendish Laboratory in the University of Cambridge from October 1967. During his stay in Cambridge he will teach only two terms out of three each year so that he can maintain his relationship with the Bell Telephone Laboratories. Dr. Anderson works principally in solid state physics.

### Edinburgh

DR. CHARLOTTE AUERBACH, at present reader in the Department of Animal Genetics, has been appointed to a personal chair in genetics, with effect from October 1.

### Manchester Institute of Science and Technology

DR. L. R. G. TRELOAR, at present reader in the Department of Polymer and Fibre Science, has been appointed to a newly established chair of polymer and fibre science.

### Nottingham

DR. J. S. L. LEACH, at present reader in physical metallurgy in the Imperial College of Science and Technology, has been appointed to the Cripps chair of metallurgy, and to the headship of the department.

## Announcements

THE Council of the Institute of Physics and the Physical Society has made the following awards for 1967: *Guthrie Medal and Prize* to Sir James Chadwick, formerly Lyon Jones professor of physics in the University of Liverpool and Master of Gonville and Caius College, Cambridge; *Glazebrook Medal and Prize* to Sir Charles Sykes of Firth Brown Limited; *Thomas Young Medal and Prize* to Professor D. Gabor of Imperial College of Science and Technology, London; *Charles Chree Medal and Prize* to Dr. J. H. Chapman of the Defence Research Telecommunications Establishment, Canada; *Duddell Medal and Prize* to Dr. K. D. Froome and Mr. R. H. Bradsell of the National Physical Laboratory; *Charles Vernon Boys Prize* to Dr. A. H. Cook of the National Physical Laboratory; *Bragg Medal and Prize* to the late Mr. D. McGill, at the time of his death organizer of the Physics Section of the Nuffield Foundation Science Teaching Project.

THE Council of the Edinburgh Geological Society has nominated Mr. W. Mykura, Institute of Geological Sciences, Edinburgh, for the Clough Award for 1966/67, in recognition of his geological work in the south of Scotland.

THE British Society of Audiology has recently been established, and the chairman of the provisional council is Dr. J. D. Hood of the Otological Research Unit, National Hospital, Queen Square, London. The aims of the society are to promote learning and advance education in the subject of audiology, to provide a common platform for discussion among the various disciplines involved in audiological work and to promote the status of audiology as a discipline. Further information concerning the society may be obtained from Dr. L. Fisch, Hearing Clinic, Vicarage Farm Road, Heston, Middlesex, or Mr. A. Boothroyd, Department of Audiology, University of Manchester, Manchester 13.

## 1967 GORDON RESEARCH CONFERENCES

	Colby Junior College, New London, New Hampshire	New Hampton School, New Hampton, New Hampshire	Kimball Union Academy, Meriden, New Hampshire	Tilton School, Tilton, New Hampshire	Proctor Academy, Andover, New Hampshire	Crystal Inn, Crystal Mountain, Washington
June 12-16	Hydrocarbon chemistry	Molecular electronic spectroscopy	Science and Technology of biomaterials	Animal cells and viruses		
June 19-23	Nuclear chemistry	Nucleic acids	Magnetic resonance	Biochemistry and agriculture	Lasers in medicine and biology	
June 26-30	Catalysis	Proteins	Cell structure and metabolism		Lipid metabolism	
July 3-7	Polymers	Coal science	Coenzymes and metabolic pathways	Chemistry of heterocyclic compounds	Lysosomes	Environmental sciences; air
July 10-14	Textiles	Statistics in chemistry and chemical engineering	Chemistry, physiology and structure of bones and teeth	Chemistry and physics of space	Biomathematics	Chemistry and physics of isotopes
July 17-21	Scientific information problems in research	Radiation chemistry	Physical metallurgy	Chemistry and physics of coatings and films	Chemistry and metallurgy of semiconductors	Molecular pathology
July 24-28	Corrosion	Organic reactions and processes	Chemistry at interfaces	Microbiological deterioration	Chemistry and physics of paper	Dynamics of quantum solids and liquids
July 31-Aug. 4	Elastomers	Steroids and other natural products	Solid state studies in ceramics	Nuclear structure physics	Chemistry and physics of liquids	Medicinal chemistry
August 7-11	Separation and purification	Inorganic chemistry	Toxicology and safety evaluations	Organic photochemistry	*	Plasma physics
August 14-18	Food and nutrition	Analytical chemistry	Chemistry and physics of solids	Photonuclear reactions	*	Laser interaction with matter
August 21-25	Ion exchange	Geochemistry	Chemistry and physics of cellular materials	Thin films	*	
Aug. 28-Sept. 1	Cancer	Science of adhesion	Chemistry of molten salts	Glass	*	

\* Week not available.

THE 1967 Gordon Research Conferences will be held in New Hampshire and Washington, between June 12 and September 1, 1967. Each conference will run from Monday to Friday each week, with meetings in the mornings and evenings. Application forms for the conferences can be obtained from W. G. Parks, Director, Gordon Research Conferences, Department of Chemistry, University of

Rhode Island, Kingston, Rhode Island 02881, and all application forms should be returned at least two months before the date of the conference. The conferences are intended to bring together scientists for discussions in the latest developments in each field, and not for the review of known information.

A NEW journal entitled "Thin Solid Films", designed to cover all aspects of the science and technology of thin solid films, is now being published by Elsevier Publishing Company.

THE thirty-second Parsons Memorial Lecture entitled "The Measurement and Control of Small Displacements", organized by the Institute of Physics and the Physical Society, will be given by Professor R. V. Jones on April 24 at the Royal Radar Establishment, Malvern. Further information can be obtained from the Meetings Officer, The Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

ERRATUM: In the communication entitled "Production of Oat Callus and its Susceptibility to a Plant Parasitic Nematode" by Dr. J. M. Webster (*Nature*, 212, 1472; 1966), the third sentence in the second paragraph should read "Glucose (20 gm/l.) or the same quantity of sucrose was used . . .".

ERRATUM. In the article entitled "Metabolism of Methylcarbamate Insecticides by the NADPH<sub>2</sub>-requiring Enzyme System from Houseflies" by M. Tsukamoto and J. E. Casida (*Nature*, 213, 49; 1967), the following corrections should be made: page 49, left-hand column, line 18, mammalian liver microsome-reduced nicotinamide adenine dinucleotide phosphate (NADPH<sub>2</sub>) system; line 23, the liver microsome-NADPH<sub>2</sub> system; line 26, insect microsome-NADPH<sub>2</sub> systems; line 37, an insect enzyme-NADPH<sub>2</sub> system. Page 49, right-hand column, line 14, the abdomen-NADPH<sub>2</sub> system; line 17, twenty-four insecticides and synergists labelled with carbon-14 were investigated. Page 50, right-hand column, line 59, the fly abdomen-NADPH<sub>2</sub> system; line 67, O-O-dimethyl. Page 51, left-hand column, line 16, (+)-trans-chrysanthemumate; line 17, allethronyl; line 21, the fly abdomen-NADPH<sub>2</sub> system; line 25, (5-allyl-1-methoxy- . . .). Page 51, right-hand column, line 2, chemicals; line 13, homogenate or microsomes of the resistant fly abdomen. Reference 7, *The Physiology of Insecta*.

## CORRESPONDENCE

## Economic Geochemistry

SIR,—In the note on January 7 (*Nature*, 213, 7; 1967), the statement that geochemistry has limited application and is still struggling for recognition is entirely erroneous.

The facts of the matter are that since the Second World War geochemical techniques have developed to the point that they are standard exploration practice in most parts of the world. At a conservative estimate, geochemical samples are being collected for prospecting purposes at a rate well in excess of 3,000,000 a year in the West, and probably nearer 10,000,000 a year in the Soviet Union.

Mineral discoveries, wherein geochemical prospecting has played a vital role, include base metal deposits in Eastern Canada and important copper mineralizations in Central Africa and the South-west Pacific area, to mention but a few.

In the academic field, applied geochemistry is now included in any comprehensive course of training in mineral exploration and a number of research centres exist in both government establishments and in the universities at home and overseas.

The foregoing in no way implies any criticism of the technical publication you mention, which gives a most interesting description of a novel method of prospecting for use in a particular type of terrain. I am quite certain that the authors would in no way subscribe to the view expressed in that part of your note concerned with the current status of applied geochemistry in general.

Yours faithfully,

JOHN S. WEBB

Department of Geology,  
Imperial College of Science and Technology.

# Who is Carl Zeiss?

by our Special Correspondent

*Jena, February.*

As a source of street names in eastern Europe, Karl Marx is rarely challenged. In the East German town of Jena, however, he is outdone by two local figures, Carl Zeiss and Ernst Abbe. Together these two created the firm of Carl Zeiss of Jena, manufacturing optical and fine mechanical instruments. Under Abbe's influence the company became philanthropic, and fits comparatively easily into the socialist system, but it has a history of adapting to circumstances. Before the Second World War, it supplied equipment to the German armed forces, as the present managers gloomily admit. Since then, they insist, no military equipment has been made at Jena. The company, now nationalized, makes 4,000 items (excluding its range of 200,000 spectacle lenses) and sells them throughout the world, despite considerable harassment in capitalist countries.

The instruments made by Zeiss of Jena fall into two categories, optical and metrological. The optical glass is made at Jena, by processes jealously guarded but which seem to owe more to 120 years of empiricism than to modern control technology. Apart from its well known microscopes—the latest, the all purpose “Nu”, operates either with reflected or transmitted light (or with both at once), has a pancratic (zoom) lens and all the usual facilities, and sells for about £2,000 in the United Kingdom—the company produces surveying instruments, refractometers, interferometers spectrophotometers, and the like. Zeiss also make binoculars and cameras, and a range of measuring equipment less directly useful to scientists.

Zeiss of Jena find it more than usually hard to trade with the West. In addition to the indignities caused by cold war diplomacy, there is confusion, to say the least of it, over the use of the Carl Zeiss name. When Jena became part of the Russian sector, a number of Zeiss workers, encouraged by the departing Americans, defected to the West. Claiming the right to move the Carl Zeiss Foundation to Heidenheim, a small town near Ulm in West Germany, the emigrées started production in Ober Kochen, and were supported by a ruling from a West German court. The range of equipment produced by Zeiss of Ober Kochen is similar but, says Jena, less comprehensive. After a difficult start, the Ober Kochen concern has flourished, aided by Jena's early pre-occupation with the eastern market. In recent years Jena has been expanding its business in the West, and this has brought the conflict into the open.

Judgments in favour of the Ober Kochen concern in West Germany, Austria and the Netherlands are balanced by judgments in favour of Jena in East Germany, Czechoslovakia and Yugoslavia. Ober Kochen does not market its products in eastern Europe, but Jena continue to market in West Germany under the trade name “Aus Jena”. Advertising by either concern, apart from adding to the legal confusion, tends to rebound to the advantage of the other side. In the United Kingdom the battle is in a state of suspended animation, after a High Court decision last year establishing the right of Jena to be represented. Ober Kochen had argued that the absence of diplomatic relations between Britain and East Germany prevented legal representation of Jena in a British Court. Jena, predictably, is full of praise for the British judicial system, and may feel sufficiently encouraged to go ahead with a full scale civil action. In the

United States the Ober Kochen concern is dominant, because Jena, unable to obtain visas to send service engineers, will sell only their smaller equipment there. In Canada, the city of Montreal was recently presented with an Ober Kochen planetarium, while the Royal Ontario Museum bought one from Jena.

Carl Zeiss of Jena occupies a special position in the East German economy. Nationalized in 1949, it employs more than 20,000 people and is the largest centre of research and development in the country. Unlike most East German concerns, it operates its own overseas marketing organization, and its success—it is the largest earner of foreign currency in the country—may enable other East German companies to obtain the same privileges. In the home market it is obliged by law to make a profit on every item it sells, but abroad this control is lifted, and Jena is able to undercut competitors, sometimes by as much as 30 per cent.

Research at Jena seems concentrated in product development. Ernst Gallerach, Director General of the company since August 1966, refuses to make any distinction between pure and applied research. “Pure science does not exist; it exists only when implemented”, he says. This means that while the firm retains its traditional strength in classical optics, it is slow to adopt anything newer. Lasers and fibre optics have been taken up rather half-heartedly, but holography is dismissed as an academic toy. For market research, the company relies on careful reading of the literature, conversations with customers and information from university scientists in East Germany. It needs to be convinced that an instrument is thoroughly reliable and commercial before it will set about designing it, and hence tends to leave important basic research work to companies in the West. The company has recently been re-organized, and as part of this plan is buying a computer from International Computers and Tabulators. Western computer manufacturers need not reach for their passports, however; Mr. Gallerach says that most future purchases by East Germany will be from the Soviet Union.

# A New University in Scotland

by our Special Correspondent

THE newest of the new universities to be created from nothing in Britain will receive its first students in September this year. The university is not English but Scottish. Its plans for academic development in the next few years are important not merely because the University of Stirling is well placed in time to profit from the lessons which have been learned in setting up other new universities in Britain, but also because those in charge, and particularly the Vice-Chancellor, Dr. T. L. Cottrell, are anxious that there should be a close integration between the teaching of science and the teaching of other material. In particular there is to be a course in technological economics intended to weld together an awareness of physical science and an awareness of the processes of applying science in industry. Although other universities in Britain are trying out schemes to leaven the teaching of science with matter from other disciplines, particularly economics, the plans at the University of Stirling go further than those elsewhere.

The university itself plans to start in a comparatively small way, with fourteen professors (most of whom have now been appointed). The first cohort of students will number a mere 150, plus 30 graduate students. The university is being created physically around a lake in a heavily wooded part of the Scottish countryside two miles north of Stirling. Fig. 1 shows the site of the university before building had begun. The university will differ from others in Britain not merely in its concern to have a course integrating science and industrial affairs but also in more general ways. For example, it is planned that the pattern of teaching shall be broken up into semesters each consisting of a 15 week period, one before and one after the winter vacation. In addition students will be required to spend at least two weeks at work in the university during the winter vacation. The result will be that if a student is to qualify for a degree, it will be possible to ask that he should have completed a certain number of semester courses.

Outwardly this means that the organization of the University of Stirling will resemble in some ways the pattern of academic life in many universities in the United States. In practice, the Vice-Chancellor intends that the contact between students and academic staff, and in particular the thoroughness of supervision, will make it possible to avoid any sense that the acquisition of seminar-courses or units will be a process comparable to the acquisition of trading stamps and other such tokens.

With luck, it is hoped that each semester course will occupy roughly the same amount of the student's time. Students will be helped to choose suitable courses by a director of studies. There will be major and subsidiary courses, the first occupying three consecutive semesters and the second two semesters. There will also be minor courses occupying merely one semester. In addition it is planned that every student shall be put through a course in "Approaches and Methods" largely concerned with the use of libraries and bibliography, communication, and what are called in the prospectus "rhetoric, logic and scientific method, statistics and social arithmetic". To complete Part I of a degree, a student will have to complete eight semester courses, which may for example mean

Fig. 1.

two major subjects and a subsidiary subject or—at the other extreme of diversity—one major, one subsidiary and three minor courses.

The second part of the degree course will make the total time three years for the general degree and four for the honours. The plans for technological economics are intended to cater for the education of people who may become administrators, operational researchers, or scientists working in industry. Naturally, the university provides more orthodox courses in biology, physics, chemistry and mathematics, and it will be interesting to see how great the demand is for the integrated course. Those taking the course in technological economics may begin with a school background of science specialization or may have had no science at school but only mathematics. All students following this programme will take a major course in economics in their first three semesters (1.5 years), two semesters of mathematics and a minor course in a subject with "introduction to techniques of industrial science" in the third semester of their stay at the university. In addition, they will follow a major course in physics, chemistry or biology or—if they have no background of science at school—in the major course "Introduction to Physical Science". The design of the Part I course is intended to enable students to switch for Part II either to a science subject or to economics if they so choose. Those wishing to continue with technological economics will finish off their degree with mathematics and statistics, a further study of economics, a continuation of their Part I science course, and special studies of industrial techniques and industrial projects.

In the planning of the course the Vice-Chancellor and his Academic Planning Board have had in mind the need somehow to train people who are skilled in science and also aware of the industrial importance of their subject. These people could go into works investigation teams, or economic planning departments in science-based industry, but there may be many other openings because, in general industry, commerce and public administration are in need of people who have a foot in each camp. But this part of the plan which the University of Stirling has designed for itself will be determined as much by circumstances, the inclinations of students, and the pedagogical innovations of the staff as by the aspirations of the planners. It is, in other words, an important and potentially illuminating experiment.

# Tertiary Structure of Ribonuclease

by

G. KARTHA  
J. BELLO  
D. HARKERCenter for Crystallographic Research,  
Buffalo, New York

A model is proposed of the polypeptide chain in bovine pancreatic ribonuclease based on a 2 Å electron density map involving 7,294 reflexions and data from seven heavy atom derivatives. The molecule seems to be roughly kidney shaped with dimensions of about  $38 \times 28 \times 22$  Å with a deep depression in the middle of one side. The model disagrees with that based on a 5.5 Å map suggested by Dr. C. H. Carlisle *et al.* (*Nature*, **213**, 557; 1967).

We started our investigations of the tertiary structure of the enzyme ribonuclease in about 1950 at the Protein Structure Project at the Polytechnic Institute of Brooklyn and have continued them in the Biophysics Department of the Roswell Park Memorial Institute since 1959. During the past four years, they have resulted in three dimensional electron density distributions of the protein molecule in the crystalline state; these maps progressively showed more detail as more X-ray diffraction data at higher resolution were used. Recently we have calculated a map at 2 Å resolution, using the data from the free protein crystal and from seven heavy atom derivative crystals. We believe that this map clearly shows the structure of the molecule. Comparison of this map with the primary structure of the protein, as elucidated by biochemical methods during the past few years, makes it possible to locate the amino-acid residues of which the molecule is made. Many of these residues, including four cystine disulphide bridges, can be located unambiguously. In contrast to myoglobin, the absence of any appreciable amount of  $\alpha$  helix makes a complete description of this molecule difficult; it must await a more detailed map. The purpose of this article is to show the general course of the polypeptide chain in the ribonuclease molecule, and to describe some features of biochemical relevance. We have also reason to believe that we have located the active site of this enzyme molecule.

## Primary Structure

All our X-ray diffraction investigations have been carried out on bovine pancreatic ribonuclease. The primary structure of this protein has been determined<sup>1</sup>, so that we know the number, nature and sequence of the amino-acids with a high degree of certainty. This covalent structure is shown in Fig. 1 and it can be seen that the protein contains a single polypeptide chain of 124 residues in a specific sequence. This chain is internally cross-linked by four disulphide bridges. The molecule does not possess any free SH or similar groups which facilitate specific heavy atom tagging for X-ray studies. Much information<sup>2</sup> from chemical investigations suggests probable non-covalent interactions between the side groups, when the main chain is folded up into its native configuration; some of these interactions seem essential for the integrity of the active centre.

## X-ray Data

Crystals of ribonuclease used in these investigations were grown from 55 per cent 2-methyl-2,4-pentanediol (MPD) at pH 5.0 (usually in the presence of phosphate buffer) and were monoclinic in space group  $P2_1$  with lattice constants shown in Table 1. There are two ribonuclease molecules per unit cell and the unit cell contains about 40 per cent by weight of the solvent. The molecular weight based on the covalent structure is 13,683.

The diffraction data were collected using either the Eulerian cradle<sup>3</sup> on General Electric diffractometers

(XRD-3, XRD-6) or, later, the G.E. goniostat. Copper  $K\alpha$  radiation was used ( $\lambda=1.5418$  Å). Earlier, the arcs were manually set from precomputed tables using the stationary crystal, stationary counter method, counting the X-ray quanta at the peak position, with intervening balanced pairs of nickel or cobalt filters (Ross filters); each counting time was 10 sec. Approximate absorption corrections were applied to the intensities. During the past year some of the high resolution data used in these investigations were measured using similar techniques but by setting the arcs by an automated XRD-5 with prepunched cards containing arc settings for reflexions sorted in an order suitable for efficient collection of data. Statistical studies of data collected from the same or similar crystals indicated an accuracy of 4–5 per cent in  $|F|$  for reflexions within the 3 Å resolution sphere. In the 3–2 Å range, however, the overall reproducibility fell to about 10 per cent, mainly as a result of the comparative weakness of many of the reflexions. A copper target was operated at 20 m.amp and 40 kVp, was used as a source of radiation. Wherever possible, measurements were extended to Bijvoet reflexion pairs to take account of anomalous dispersion.

## Structure Determination

Attempts were made to determine the structure of ribonuclease by means of the method of multiple isomorphous series<sup>4</sup>—a technique which had led to the solution of the myoglobin<sup>5</sup> and lysozyme<sup>6</sup> structures. A search for suitable heavy atom derivatives, conducted over the past few years, revealed a few likely ones, some of which, though satisfactory for low resolution work, were either not easily reproduced or not suitable at 2 Å resolution. Thus not all the derivatives used in computing the 4 Å map except the *cis*-diglycine platinum (CDG) were used in the later investigations. This (CDG) derivative contained two main heavy atom sites per molecule; anomalous scattering measurements were made in this case. The 2 Å map also included isomorphous derivative data from five other crystals and limited data to 3 Å from *tris*-(ethylenediamine) platinum (IV) chloride (TEP) for which the anomalous scattering data had been measured earlier.

During the course of the past 3 years, electron density maps were prepared at four resolutions and a summary of these maps is given in Table 2. It is emphasized that some of these derivatives had heavy atoms in similar positions, and the similarity of the derivatives in some

Fig. 1. Covalent structure of bovine pancreatic ribonuclease. (After ref. 1.)

pairs is so great that one could even have replaced the two independent sets of results by a single one. In fact this was done for the two sets of data for CDG derivatives (soaked in different concentration) in the 2 Å map, even though they were treated as independent derivatives in the 2.4 Å map. Table 3 gives a list of the derivatives, the heavy atom sites and occupancies used in the phase evaluation for the 2 Å map. These heavy atom positions were determined and refined by Patterson, difference Fourier and least squares methods<sup>8-10</sup>. The protein phase angles were evaluated by a combination of isomorphous series and anomalous dispersion data<sup>11,12</sup> from the different derivatives, taking care to give proper weights to the

phases obtained using any given derivative, and to the reliability of the data from that derivative. The Fourier maps were computed in *xy* or *yz* sections and the results printed out in coded form suitable for direct contouring on the output sheets from the IBM 7044 computer.

Many features of the molecule are visible in the 3 Å model computed with 2,340 protein reflexions: (a) the position of the amino end which sticks out quite independently of the rest of the molecule; (b) the depression on the surface of the molecule where the phosphate ion is located (as will be shown later); (c) the position of three S-S bridges of high density near which the main chain density shows the topology expected in these

Table 2. PROGRESS IN FOURIER RESOLUTION OF ELECTRON DENSITY MAPS ACHIEVED IN THIS INVESTIGATION

Date	Resolution	No. of "reflexions" used in map	No. of derivative crystals from which data were collected and used in phase evaluation. At higher resolution only some had their anomalous scattering effects measured	No. for which anomalous scattering was also used	Comments
July 1963	4 Å	1,020	7	7	Shown general shape of molecule and also two regions of high density which looked like S-S bridges
June 1964	3 Å	2,340	In addition to above data from seven derivatives, isomorphous series and anomalous scattering data from CDG and TEP	2	Shown molecular boundary, three S-S bridges, amino end of chain and, later, we could also infer the position of the active site from arsenated RNase
Aug. 1966	2.4 Å	4,895	Data from eight derivative crystals including two separate sets of measurements for CDG	1	All S-S bridges now unambiguous. Whole of main chain could be traced with reasonable certainty, except for a few regions of ambiguity
Dec. 1966	2 Å	7,294	Data for seven crystals; the two separate sets of CDG data were combined into one	1	Ambiguities in tracing the main chain are removed and we can locate all residues with a reasonable degree of certainty

\* Each "reflexion" combines information from several derivatives.

regions. It was also seen that the region near the amino end is partly helical and that the molecules are well separated by regions of very low density.

The 2 Å map involving 7,294 reflexions and data from seven derivatives was computed in sections of constant *z* at intervals of *x*/60, *y*/88 and *z*/112—these intervals were

so chosen that the printed output had a scale of 1 cm to an angstrom. No *F*(000) term was added to the series and the contours were drawn on an arbitrary scale of 3 units, with the first contour corresponding to 3. In this scale the disulphide bridges had a density in the range 22–17—the only other peak which had a value of more than 17 in the present map was near the main chain at a region close to the residue 46, and this region had a peak value of 19. The region between the molecules rarely rises to more than contour level of 3 and there are no regions of large negative density.

A schematic drawing of the main chain as deduced from the 2 Å contour map appears in Fig. 2. Starting with the amino end, which was quite easily seen even in the 3 Å map, it is possible to proceed along a ribbon of high density corresponding to the main chain by counting along it at appropriate residue distances and using the positions of bulky side groups as a check. In this way it was possible to proceed up to the carboxyl end of the chain, and the four disulphide bridges and their known positions in the amino-acid sequence in Fig. 1 acted as a good check in case any adjustments were needed. At the scale (1 cm=1 Å) to which the map was drawn it was not easy to recognize all the side groups purely from the shape of the contours, but most of the bigger side chains could be identified by their bulk. It is hoped that the larger scale model now under construction will make it possible to recognize independently many of the side groups by their shapes and bulk. The present map has only been used to trace the course of the α-carbon atoms of the main chain assuming the correctness of the covalent structure of Fig. 1. No attempt has been made at present to check the correctness of the chemical sequence by identifying the side groups from X-ray data alone.

Fig. 2. Schematic diagram of the main chain folding in the ribonuclease molecule. (Thanks are due to Mr. John C. Wallace, who drew from the model.)

### Conformation of the Main Chain

The molecule is roughly kidney shaped with approximate dimensions of  $38 \times 28 \times 22$  Å with a deep depression in the middle of one side. Two of the disulphide bridges (26-84) and (40-95) are on one side of this constriction and the other two (58-110) and (65-72) are close together and on the opposite end. Between these two ends the main chains run in three roughly antiparallel sections; the sections between residues 40-58 and 98-110 running in one direction and region 75-90 running in the opposite direction. Quite clearly the molecule has comparatively low helical content. The only obvious helical segment is about two turns in the region of 5-12 near the amino end and possibly two turns each in the regions 28-35 and 51-58, even though the latter are not quite obvious. There are a couple of other regions where there is a suggestion of helical conformation.

The molecule clearly has a much more exposed structure than myoglobin; the smallest of the dimensions is about 20 Å, and no part of the molecule is shielded from the surrounding medium by more than one layer of main chain. This makes it necessary for some of the hydrophobic side chains which would otherwise be shielded from the solvent to lie near the surface. As a general rule, however, most of the segments which consist predominantly of polar side groups—as, for example, residues 66-71 and 85-91—do show up clearly at the outside of the molecule with their side groups pointing outwards into the solution.

### Location of the Active Site

From an examination of the position of the phosphate ion in crystalline ribonuclease, we now have indirect information about the location of the site of enzymatic activity of the molecule. The position of the phosphate ion was first established by crystallizing ribonuclease from a solution containing, not the usual phosphate group, but the electrostatically very similar arsenate group. The resulting crystal was very closely isomorphous with the phosphate crystal. An electron density difference map computed between the phosphate and arsenate crystals at a resolution of 4 Å, and using the known protein phases, resulted in a single peak per asymmetric unit on a very clear background. The position of the arsenate group was also established independently of any knowledge of the protein phases from a three dimensional difference Patterson map using data from the phosphate and arsenate crystals. The location of this region with respect to the protein molecule showed that the phosphate is embedded in the depression of the kidney-shaped surface of the molecule.

In fact, the isomorphism between the phosphate and the arsenate crystals was so good that, despite the fact that the actual electron density difference between an arsenate and phosphate group is not very large, complete three dimensional X-ray data were collected for the arsenate crystals, and these data were used as heavy atom derivative crystal data for protein phase angle evaluation.

### Comparison with Chemical Evidence

Assuming that the active site is indeed near the location of the phosphate ion—an assumption for which there is much chemical evidence and which we can use as a plausible hypothesis—we can locate the regions of the main chain and the amino-acid residues surrounding it. These residues are shaded in Fig. 1. These regions occur at different parts of the main chain, and detailed examination of the characteristic arrangement creating the required charge distribution, and other side chain interactions in this region, is likely to throw some light on the nature of the active site. Even though in our map we are dealing with an arrangement which results when a phosphate ion is bound at the active site, it is possible that the mechanism of attachment and the conformation

around this region will not be very different when other substrate analogues are bound there.

It is seen that the residues closest to the phosphate are residue 119 near the carboxyl end and residue 12 near the amino end. Both of these are histidines, and much chemical evidence<sup>13,14</sup> indicates their close relationship with the activity of the molecule<sup>15</sup>. Other residues further out, but which might be of importance, are lysine 7, lysine 41, histidine 48, all of which are reasonably close to the phosphate site. It is also seen from the present map that the amino end residues up to 21 or 22 stand out clearly apart from the rest of the molecule, except for the region near about histidine 12 which comes close to the active site forming its third side. This agrees well with the possibility of cleaving off of this part of the chain by the enzyme subtilisin, leaving the rest of the molecule basically undisturbed.

A fuller description of the ribonuclease molecule and a comparison of the intramolecular relationships of the functional group with chemical evidence for active site groups, intermolecular contacts, and solvent interactions are at present being prepared. Furthermore, we are also preparing a fuller description of the heavy atom "dyes", their preparation and mode of use as well as X-ray diffraction techniques used in the solution of the structure.

We thank the Dean Langmuir Foundation, the Rockefeller Foundation, and the Damon Runyon Foundation for providing the initial support of this project, and the National Science Foundation and the National Institutes of Health for continuing support during recent years. The Roswell Park Memorial Institute and the New York State Department of Health, as well as the Roswell Park Division of Health Research Incorporated, all contributed to the success of this venture by providing space and computing facilities.

In the early days of the work on the structure of ribonuclease, important contributions were made by several scientists no longer connected with this project; among them the following deserve especial mention and thanks: Dr. B. Magdoff, Dr. V. Luzzati, Dr. M. V. King, Dr. A. Tulinsky, Dr. E. von Sydow, Dr. F. H. C. Crick, Dr. T. C. Furnas, jun., Dr. R. Worthington, Dr. A. DeVries, Dr. D. Harris, Dr. H. H. Mills, Dr. R. Parthasarathy and Dr. R. Davis.

We also thank the following assistants: Miss F. Elaine DeJarnette for mounting protein crystals and for collecting most of the X-ray diffraction data during the past six years; Mrs. C. Vincent and Miss K. Go for assisting in data handling and in drawing electron density maps and constructing models; Mrs. Theresa Falzone for excellent assistance in the preparation and for handling the crystals and heavy atom dyes; Misses Elsa Swyers and Sylvia Scapa for preparing some heavy atom dyes; Mrs. Edith Pignataro for collecting data while the project was at the Polytechnic Institute of Brooklyn; Mr. W. G. Weber for constructing, and to some extent designing, the mechanical parts of the single crystal counter X-ray diffractometer.

## BOOK REVIEWS

### KILMISTER ON EDDINGTON

Sir Arthur Eddington

By C. W. Kilmister. The Commonwealth and International Library of Science, Technology, Engineering and Liberal Studies: Selected Readings in Physics.) Pp. vi+279. (London and New York: Pergamon Press, Ltd., 1966.) 21s. net.

SIR ARTHUR EDDINGTON was born in 1882 and died in 1944. Thus, he lies in the middle distance historically, a man of the age of relativity and quantum theory, but unaware of modern developments in those fields. For him there were two elementary particles, the proton and the electron. How are we to classify him, as ancient or modern? Has the acceptable part of his contribution been absorbed into the stream of science, and the unacceptable part put away in storage for historians of science to mull over as the freakish product of a freakish mind? If Eddington had been dead for a hundred years, one might attempt some such dogmatic classification, but he is too recent for that, and so one welcomes this book by Professor Kilmister as of great assistance in the assessment of Eddington.

The general title of the series to which this book belongs is *Selected Readings in Physics*, and so it is appropriate that more than two-thirds of the book consists of excerpts from Eddington's writings, selected to cover his wide range of interests. There are four extracts from *Internal Constitution of the Stars*, one from *Mathematical Theory of Relativity* (a long extract giving Eddington's generalized theory), one from *Relativity Theory of Protons and Electrons* (here the Riemann-Christoffel tensor plays a central part), and one from *Fundamental Theory*. Three papers are reproduced: *On the Derivation of Planck's Law from Einstein's Equation*, *The Factorization of E-Numbers*, and *The Pressure of a Degenerate Electron Gas and Related Problems*. Finally, there is a *Manuscript on the Transfer Problem*.

Most of these extracts are prefaced with explanatory remarks by Professor Kilmister, but his real task of explanation is undertaken in the first third of the book. This consists of a number of chapters referring to the extracts already mentioned, but tied rather loosely to them. This provides a very happy arrangement. Had Professor Kilmister tied his remarks closely to the text of Eddington, elucidating this point or that, the result might well have been extremely dull. He elected, however, to dig a little deeper and lay the foundations in his own way. As his ideas about groups and algebra are clearer and more sophisticated than Eddington's, he is able to illustrate complicated situations by simple but pertinent examples. Further, he rivals Eddington in directness and vividness of style. If I were a student, coerced into reading this book for the good of my (scientific) soul, I would spend my time on Kilmister and skim through Eddington. It is not that what Kilmister says is always transparently clear. One feels, however, that there is bedrock somewhere, and from that bedrock argument can be maintained. With Eddington, one is in danger of being swept into a whirlpool of confusion with no rational bottom, or, if there is one, my toes are unable to reach it.

In thinking about Eddington, my mind goes back to the two occasions on which I met him. The first was in Dublin in 1929 or 1930, when we were guests at dinner in the house of Professor John Joly. In the course of conversation, I expressed contempt for Williamson's *Differential Calculus*, long the text-book recommended to students in Trinity

College, Dublin, but sadly lacking in mathematical rigour. Eddington disagreed; he had been reared on Williamson and found no fault with it. I understand better now what he meant. He was an intuitionist. He felt things in his bones, and was impatient of delta and epsilon. Unfortunately, tedious as logically precise discourse may seem, it is the only universal language, and it may be that Williamson is to blame for those obscurities which, as Professor Kilmister very readily admits, render some of Eddington's ideas almost impossible to understand.

A chapter is devoted to *The Gulf between Relativity Theory and Quantum Theory*. Having shown how Eddington proposed to bridge the gulf by means of the Riemann tensor, the 256-fold algebra and linear tensor identities, Professor Kilmister ends the chapter as follows: "The next task was to find a problem which could be treated by these methods. The Einstein universe was selected because it was simple in both theories. The puzzling thing for the reader, however, is that Eddington never gives any straightforward prescription of exactly how the analysis is to be carried out. Even when we have progressed as far as this, we have still not formulated any comprehensive theory in terms of which to do the calculations. These calculations still rely on the art and intuition of the theorist, and it is not easy for others than Eddington to provide this intuition".

The second occasion on which I saw Eddington was some years later in Toronto. He gave a popular lecture on cosmology to a large audience. It was, of course, an excellent lecture, but I was puzzled by the fact that he lectured with one hand behind his back. Then, at the appropriate moment, the hand came forward and raised into the air an orange, illustrating excellently a manifold of constant mean curvature but with many minor corrugations.

The only criticism I have of the extracts selected by Professor Kilmister is that there is none to illustrate the playboy in Eddington. The cover of this book shows a grim-faced Eddington and inside there is reproduced a chalk drawing by Augustus John, less grim but sadder. In the Kingdom of Heaven there is no laughter, and little among scientists, for laughter is caused by the juxtaposition of irreconcilables. In Eddington we find the irreconcilables—the showman's flair on the one hand, as evinced by the orange, or, more generally, by his popular writing, and, on the other hand, his lonely quest into the deepest secrets of nature. I like to think of him now resting on some cloud and shaking with quiet laughter. Eddington was a man who could talk low and talk high, but eschewed the middle-talk which is the currency of most scientists.

Professor Kilmister is to be congratulated on a most interesting book. It contains, I should add, a bibliography of works by Eddington and about him. J. L. SYNGE

### EARLY TYPE STARS

The Early Type Stars

By Anne B. Underhill. (Astrophysics and Space Science Library, Vol. 6.) Pp. xiii+282. (Dordrecht: D. Reidel Publishing Company, 1966.) 52 D. florins.

As a comprehensive review of the present state of knowledge regarding early type stars, both observationally and theoretically, this volume will be essential for many more astronomers than those working directly in the field. Indeed, there need be no restriction to astronomers only, for Miss Underhill briefly but efficiently sketches in the basis of each aspect of the study of these stars without presupposing expert knowledge of astronomy, before going into great detail concerning the observational material in particular.

The study of early type stars is very important because, as the most massive ordinary stars known, they are at the

same time the most luminous and the shortest-lived. Consequently, they are ideal for the study of the spiral arm structure of our galaxy; their great luminosity makes them important as distance indicators for other star systems and in studies of interstellar absorption; while their short lifetimes make them sensitive tests of theories of star formation and evolution. In addition, recent work on quasars and blue stellar objects has revealed the depth of our ignorance concerning the distribution of blue stars in the outer parts of our galaxy.

Chapters on spectral classification, photometry, binary stars and spectral analysis are relevant to all types of stars, while that concerning the details of the helium spectrum illustrates the atomic theory of the formation of spectral lines in stellar atmospheres. In the later chapters, several special varieties of early type stars are considered, such as Wolf-Rayet and shell stars, which are as yet little understood theoretically.

With a writer who has herself done so much fundamental research in the field, it is inevitable that personal opinions are sometimes apparent. These, however, only serve to add interest to the book, and to emphasize how much work remains to be done before we have a reasonably complete understanding of the subject. Many of the relevant basic data have been collected and reproduced in tables throughout the book, greatly enhancing its value to the non-expert, and the quality of the diagrams and reproductions of spectra is very high. Only the rather flimsy binding must be criticized, particularly in what should become a standard work. A very thorough list of references completes a book which, in bringing together much diverse information on one topic, should lead to much fruitful research.

R. D. CANNON

## OCEAN WAVES AND TURBULENCE

### The Dynamics of the Upper Ocean

By O. M. Phillips. (Cambridge Monographs on Mechanics and Applied Mathematics.) Pp. vii+261. (London: Cambridge University Press, 1966.) 60s. net.

THIS elegant book—more elegant than its subject—points to the progress since Ursell's devastating survey appeared in 1960. Many of us will find Phillips's coherent account a very useful guide to some recent work of Longuet-Higgins, Benjamin, Miles and to his own very considerable contributions.

The first three chapters develop the required hydrothermodynamics, allowing for stratification (heat and salt) and rotation. The underlying theory of surface waves includes the simpler non-linear solutions, yielding certain results concerning surface and bottom streaming, the depression of the mean water level over a sloping shelf, and bottom pressure fluctuations in deep water (pertinent to microseisms). The way is now clear for the three main topics: ocean surface waves (eighty-two pages), internal waves (thirty-two pages), and oceanic turbulence (forty-five pages).

The chapter on ocean surface waves, after some preliminary definitions and discussion of various spectral estimates, gives a systematic and combined treatment of the wave generation theories by Miles and Phillips. The apparatus needed here is substantial, yet I am not convinced that the age-old problem of how the wind generates waves is now essentially solved. In comparison, the subsequent discussion of the saturated frequency spectrum ( $\sim n^{-5}$ ), a concept introduced by Phillips, is far simpler and far more rewarding. The role of ripples is emphasized, and the effect of the waves on the wind (profile and drag) receives attention. The chapter closes with a discussion of departure from Gaussian statistics.

The chapter on internal waves introduces into the study of higher modes some of the statistical considerations which have been so rewarding in the study of the lowest (or

surface) mode. Approximate solutions are derived for the cases that the wave lengths are long or short as compared with the characteristic thickness of the thermocline. In the short wave limit the presence of a weak shear will twist the wave so as to produce an equilibrium spectrum  $\sim n^{-3}$ . In the long wave limit the self shear and stratification conspire to produce spectral densities  $\sim n^{-1}$  or  $n^{-3}$  according to whether the thermocline depth is small or large relative to wave length. The arguments that lead to these relations are fascinating, and the results can be reconciled with observations, but far more definitive observations are required to put these developments on a sure footing. The last section gives a very nice compact survey of the combined effects of stratification and rotation. The co-ordinates in figure 5.10 reveal the author's native hemisphere and discriminate against his northern hemisphere readers.

The final chapter on oceanic turbulence reviews the fundamentals of statistical turbulence theory. It is pleasant that the best confirmation of the Kolmogorov prediction derives from oceanographic measurements (Grant, Stewart, and Moilliet). A principal task here is an assessment of the limitations and modifications imposed by stratification on the isotropic theory. The Monin-Obukhov and Ekman depths define various pertinent layers, and the wave number  $\kappa_b \sim N^{3/2} \epsilon_0^{-1/2}$  separates the inertial from the buoyancy sub-range in the spectrum. Oceanic measurements bearing on these central concepts simply do not exist. In the closing discussion of entrainment and thermocline formation the lack of definitive measurements is even more limiting.

The author's choice of words is delightful: he speaks of "parasitic capillaries", of "foam patches marking the demise of crests that had previously broken", of "the strong, promiscuous interactions" of the turbulent Fourier components, contrasting with "the weak, selective interactions" of the internal gravity waves.

The book emphasizes how much has been accomplished in developing a formalism appropriate to the messy, symbiotic processes in the oceans; yet how little in measuring the pertinent parameters with adequate spacial and temporal resolution. I find the title "The Dynamics of the Upper Ocean" to be at once too specific and too general: too specific because so much of the last two chapters is pertinent to the abyssal oceans; too general because the dynamics of upwelling, of the general circulation, boundary currents, planetary waves is lacking. There is virtually no overlap with Stommel's book on the Gulf Stream, which also deals with ocean dynamics. Phillips's emphasis is on perturbation methods pertinent to ocean processes, and here his original and coherent account is a most welcome contribution.

W. MUNK

## RADIATION BELTS REVIEWED

### Radiation Trapped in the Earth's Magnetic Field

Edited by Billy M. McCormac. (Proceedings of the Advanced Study Institute held at Chr. Michelsen Institute, Bergen, Norway, August 16–September 3, 1965.) Pp. xiv+901. (Dordrecht: D. Reidel Publishing Company; New York: Gordon and Breach, 1966.) \$45.

THIS Advanced Study Institute was held seven years after Van Allen's discovery of the radiation belts, and the Proceedings disclose and describe the vast amount of information concerning the belts that has been obtained in that time. Particle measurements already represent a substantial survey, covering essentially the whole spatial region of trapping. In energy there is one important gap for protons below 100 KeV. It is expected that such protons are the most important source of the "ring current", which is jargon for the current causing the main phase of storms. The important temporal variation is that of the solar cycle and, whereas the original dis-

covery was made at the time of the strongest ever solar maximum, the great majority of measurements are recent and therefore at solar minimum.

Nevertheless, one important feature of the solar cycle variation is revealed in one of the few European contributions. Comparison of results from *Ariel I* and *Explorer IV* shows that the intensity of the inner belt increases with solar activity and, since it is known that the lifetime of trapped particles decreases, the source must increase substantially. On the other hand, the earliest suggested source, neutron albedo from cosmic rays, should not vary. Other aspects discussed by theorists led to one of the principal conclusions of the institute—that neutron albedo is a very minor source and that most of the particles come from the solar wind.

It was also appreciated that stochastic acceleration was of outstanding importance and this was emphasized in the discussions. It was seen that future progress in the comprehension of the radiation requires much greater effort in measuring disturbances in the electromagnetic field, which has been neglected in comparison with the particles. Furthermore, it is important to separate space and time variations and this requires multiple satellites, as emphasized in the excellent summary at the end of the Proceedings. One paper on plasma instabilities was included, and at the sequel at Munich this year (1967) much more of the programme will be given to waves, for it has been realized that the radiation belts provide a splendid opportunity for observing plasma behaviour. The last one-third of the Proceedings under review is concerned with radiation belts created by nuclear explosions and with the effects of trapped radiation on electronic devices and humans.

J. W. DUNGEY

## MATHEMATICAL PHYSICS

### Problems of Mathematical Physics

By N. N. Lebedev, I. P. Skalskaya and Y. S. Uflyand. Revised, enlarged and corrected English edition translated and edited by Richard A. Silverman. With a Supplement by Edward L. Reiss. (Selected Russian Publications in the Mathematical Sciences.) Pp. xi+429. (Englewood Cliffs, N.J., and London: Prentice-Hall, 1965.) 96s.

THIS is a collection of more than 600 exercises on methods of mathematical physics, with equal emphasis on both parts of the term. Solutions, covering 105 pages, are supplied for a representative fraction of the problems. The subject matter is mathematical physics of the strictly classical kind, with problems on elasticity, electromagnetism, fluid dynamics, heat conduction and diffraction of waves; there are none on quantum mechanics. The problems are classified mostly according to the mathematical methods rather than the field of physical application, with chapters on hyperbolic and elliptic equations, discrete and continuous Fourier and eigenfunction expansions, and a brief chapter on integral equations. Each chapter starts with a brief introduction, reviewing the key points to be used in the problems, and closes with a bibliography for further reading which is both carefully chosen and sufficiently short to be useful. (The translator says that the references in the original Russian version have been revised and brought up to date for the English edition.) There is a helpful supplement by Reiss on variational and related methods, contrasting in its emphasis with the original text, which concentrates on exact solutions.

A preparation not far short of degree level in mathematics with a large share of physics would be necessary to gain much benefit from the book, but anyone at about that stage who has worked through the first volume of Courant-Hilbert and wishes to develop his ability to set up problems and his dexterity to solve them could scarcely

do better than to settle down with the book for a vacation. The book should also serve as a useful source of examples for lecture courses. The production and printing are excellent.

A. HERZENBERG

## VACUUM SEALS

### Vacuum Sealing Techniques

By A. Roth. Pp. xiv+845. (London and New York: Pergamon Press, Ltd., 1966.) 240s. net.

THIS relatively large book supported by nearly 1,700 references represents a collection of a large number of items dealing with vacuum technology that have been reported previously. In making such a collection, the author has necessarily had to cover a number of aspects in insufficient detail for the book to serve in itself as an immediate reference for the reader wishing to construct anything but the simplest piece of vacuum equipment. For example, the section devoted to brazing, which is an important vacuum sealing technique, is restricted to some twenty pages of the chapter devoted to permanent seals. This chapter deals with welded joints in a similar manner, but glass seals, to both glass and metal, are dealt with more fully, and some information on simple glass working is included. There are also some details of metal ceramic sealing techniques and, surprisingly in this chapter, a short section on elastomers and plastic pipes. Appropriately the chapter closes with sections on the techniques for the sealing off of glass, quartz and metal tubulations.

The next chapter is of similar length and concerns semi-permanent and demountable seals; it covers the use of waxes, epoxy resins, soft solders, solder glasses, ground glass joints, liquid seals and gaskets. A large number of the techniques described, however, would be obvious to anyone with normal laboratory experience. Also included is a considerable amount of information on the types of elastomer, metal gaskets and seatings available commercially. The task of choosing from this information could be somewhat bewildering to someone starting in the vacuum field, while it would be superfluous to the practising engineer or physicist, who will have his own preferred designs selected from components readily available to him. Chapters devoted to the transmission of electricity and mechanical motion through vacuum seals give a number of methods that can be used when limited facilities are available, together with commercially available items.

The use of metal ceramic seals for electrical lead-throughs receives only passing mention, which is unfortunate in such a book in view of their ruggedness and increasing use in the vacuum field. Transfer of materials into vacuum is almost entirely restricted to gaseous matter using components from simple laboratory apparatus to commercially available valves. The final chapter is devoted to some of the seals used in the transmitting of radiations other than radio frequency radiation.

F. BROOK

## FERTILE SOIL

### The Control of Soil Fertility

By G. W. Cooke. (Agricultural and Horticultural Series.) Pp. xvii+526. (London: Crosby Lockwood and Son, Ltd., 1967.) 70s. net.

IN writing this book, Dr. Cooke has made a most valuable and balanced contribution to the literature of soil science. It is not competitive with Russell's *Soil Conditions and Plant Growth* but complementary, because it bridges so effectively the gap between the more fundamental aspects of soil science and farm practices. As a consequence of this and also of the way that it is written, this book will

be of value to progressive farmers as well as to students of agricultural science who will use it as a standard text.

One of its most impressive features is the masterful way that Dr. Cooke has married the lessons of the long-term classical soil fertility experiments, especially those at Rothamsted, with the results of more recent experimentation not only in Britain but also abroad. A huge volume of literature, much of it of very recent origin, has been consulted and the essential features of it have been combined under appropriate chapter headings. This has resulted in some overlapping between chapters, but the small amount of repetition is not detrimental because each chapter can be read as one of a series of complete essays. After all, it is unlikely that anyone, except a conscientious reviewer, will want to read the book from cover to cover within the space of a few days. For most it will be an authoritative book of reference to be consulted in respect of its separate parts, and good indexing adds to its value in this respect.

The book is strongest in those parts concerned with arable crop production, and this is understandable because the end products are so easily measurable in contrast with those of grassland, where there is the complication of the grazing animal as a middleman in the production process. It is not enough to talk about fertilizer responses in terms of additional grass dry matter, for one must also have some account of the value of these in terms of milk or meat. The present situation is complicated by the convention, when assessing the value of grass which is fed in association with concentrates, of making it the residuary legatee of any errors of calculation which are based on the attainment of theoretical feeding standards. Dr. Cooke cannot be blamed for this because he can do no more than make the most of available information. In doing this he has drawn attention to the considerable deficiencies of knowledge in fertilizer practice for pasture and the need for more critical methods of assessing pasture productivity.

The penultimate chapter, dealing with relationships between organic matter and soil productivity, is particularly valuable because it is such an objective analysis of knowledge on a topic which so often creates emotional rather than factual argument. It is the best balanced discussion of this subject that has been published, but this can also be said of many of the chapter headings. It is a really authoritative book and its author has just cause to be proud of it.

M. M. COOPER

## PRESERVATION BY IRRADIATION

### Food Irradiation

(Proceedings of the International Symposium on Food Irradiation jointly organized by the International Atomic Energy Agency and the FAO of the U.N., and held in Karlsruhe, June 6-10, 1966.) Pp. 956. (Vienna: IAEA; London: H.M.S.O., 1966.) 517 schillings; 141s. 2d.; \$20; 80 D.M.

THIS symposium reviewed developments in the whole field of food irradiation which have taken place since the similar meeting in 1958. The symposium was optimistic, for developments have on the whole been favourable.

The fundamental difficulties of the process of food irradiation have still not been overcome. The chief fundamental advance has been the demonstration that irradiation at temperatures below  $-20^{\circ}\text{C}$  reduces undesirable side effects to about one-third, which made possible the U.S. Army's plans for the sterilization of meats.

Nevertheless, the limitations are now better understood and, even accepting them, there is an already large list of potentially useful treatments. Furthermore, it is increasingly understood that feasibility must be regarded against alternative practices and, where this has been done, it seems that several irradiation processes might

be economically viable. Above all, the vast American programme of feeding irradiated foods to mammals has not yielded evidence of harmful effects, other than loss of vitamins comparable with canning; and a similar smaller programme in Britain gave similar results. The U.S. and Canadian authorities have permitted irradiation of particular foods, with more in prospect; and legislators in other countries are actively considering how to deal with the situation. While there have been substantial international exchanges, such as this symposium, where uniformity of view on technical matters has been sought, the conference noted the lack of similar attempts on the legislative plane, though this seems necessary to facilitate potential international trading in irradiated foods.

Several outstanding points of technical difficulty are evident in these proceedings, besides the obvious need to diminish the side effects and increase the microbicidal power of irradiation. These difficulties are the especially poor control by irradiation of viruses and enzymes; the significance of conceivable mutations in micro-organisms causing food poisoning; the discrepancy between the toxic effects of irradiated nutrients on single cells and the absence of corresponding effects in animal feeding trials; and the difficulty of detecting whether a food has been irradiated. The general impression is, however, that many possible processes would not be seriously affected by these difficulties, and that applications are likely in many countries as soon as the laws are regularized.

M. INGRAM

## EARLY PREGNANCY

### Pre-implantation Stages of Pregnancy

Edited by G. E. W. Wolstenholme and Maeve O'Connor. (Ciba Foundation Symposium.) Pp. xii + 430. (London: J. and A. Churchill, Ltd., 1965.) 65s.

THIS book is an account of the proceedings of one of the many small international conferences on a variety of topics of biological and medical research, which have been convened by the Ciba Foundation. This particular symposium was held in April 1965, under the distinguished chairmanship of Professor C. H. Waddington, and the resulting volume contains sixteen contributions on many different aspects of the pre-implantation stages of mammalian development.

The first two papers deal with the ultrastructural changes which occur in the egg during fertilization, and with the fine structure of the blastocysts of selected mammalian species. Others deal with energy metabolism, nucleic acid and protein synthesis, genetic aspects and the influence of various maternal factors on early embryonic development.

The short discussions which follow each paper that was read and the more extensive general discussions are quite as interesting as the papers themselves, and contribute substantially to the value of this interesting book.

B. MORRIS

## OBITUARIES

### Professor J. W. Heslop Harrison

PROFESSOR JOHN WILLIAM HESLOP HARRISON died at his home in Birtley, Co. Durham, on January 23, 1967, the day after his eighty-sixth birthday. Harrison was emeritus professor of botany of the Universities of both Durham and Newcastle upon Tyne.

He received his early education at Rutherford College, Newcastle upon Tyne, and in 1903 graduated B.Sc. from

Armstrong College in the University of Durham, with distinction in chemistry. He was science master at Middlesbrough High School between 1905 and 1917. During this time he obtained his M.Sc. and D.Sc. for research on the biology and systematics of species and hybrids, mainly of the Geometrid sub-family Bistoninae. He then joined the staff of Armstrong College and in 1920 was appointed lecturer in zoology. In 1926 he became the first reader in genetics in the University of Durham at Newcastle, and from 1927 until his retirement in 1946 he was professor of botany in Armstrong College (later King's College). From 1940-50 he was very active as secretary of the University of Durham School Examinations Board; he built up a relationship between the examining board and the grammar schools of the four northern counties which has been widely acclaimed by the heads and teachers of the schools.

In 1921 he was elected a Fellow of the Royal Society of Edinburgh and he became a Fellow of the Royal Society of London in 1928. He served on the Council of the Edinburgh Society for several periods and he was vice-president from 1945-48. He was on the editorial committee of the *Vasculum* from its foundation in 1915, and he was the sole editor of the *Vasculum Substitute* from 1942 until his death. He was also one of the original founders of the Northern Naturalists Union in 1924, and he held continuous office in this society, also until his death. After his formal retirement in 1946 Harrison held a senior research fellowship until 1949 in the agricultural faculty of King's College, Newcastle, and he was a member of the board of the faculty of agriculture until he died. Even after 1949 he continued to give courses of lectures, mainly on genetics, to agricultural and other students.

Harrison was a gifted biologist and field naturalist. His memory for biological facts was prodigious and his knowledge of flowering plants and insects was of a most unusual depth and understanding. Harrison published more than 500 papers and many thousands of biological records in the *Vasculum*, the *Entomologist* and similar journals. His chief research centred on evolutionary topics and he was particularly active in the years when Darwinists and Lamarckists fought almost pitched battles. He contributed to both sides and he was also a staunch mutationist. His work in these fields helped to lay the foundations for much future research when the processes of organic evolution were becoming better understood. In particular Harrison, by his work on the occurrence, significance and induction of industrial melanism in moths, set the pace for the future understanding of these phenomena. Harrison published his chief papers in studies of the Bistoninae, on the effects of chemicals on the insects *Selenia bilunaria* and *Tephrosia bistortata* and on the egg-laying insects of the sawfly, *Pontania salicis*. On *Selenia* he worked at first with F. C. Garrett, and he claimed to have induced mutations; he was thus among the first to induce mutations. He claimed that his work on *Pontania* showed a Lamarckian effect, and although this work has not been repeated neither has it been disproved. Harrison also worked on the systematics, cytology and genetics of the genera *Rosa* and *Salix*, and, to a lesser extent, *Rubus* in conjunction with Dr. Kathleen B. Blackburn.

In 1934 Harrison visited the Isle of Raasey with Professor A. D. Peacock of University College, Dundee, and the following year he initiated his own expeditions to many islands of the Inner and Outer Hebrides. Official parties from King's College, Newcastle, under Harrison visited these islands once or twice a year from 1935 to 1946. After 1946 Harrison continued his visits until about 1962. During these expeditions a thorough and systematic study was made of the flora and fauna (chiefly insects) of the Hebrides, and many finds and new records were made. Most of the results of this work were published in a series of papers in the *Proceedings of the University of Durham Philosophical Society*.

Harrison will be remembered for his scientific work which has become part of the history of evolutionary biology, but he will be particularly remembered for his wonderful gift of teaching.

P. G. FOTHERGILL

### Professor F. C. Ormerod

FRANK ORMEROD, emeritus professor of laryngology and otology in the University of London, died at his home in London on January 25 at the age of 72.

Educated at Manchester Grammar School, he graduated M.B., Ch.B., at the University of Manchester in 1916; then followed three years of service with the R.A.M.C. in Mesopotamia and Afghanistan. He graduated M.D. in 1920, became F.R.C.S.Ed. the following year and F.R.C.S. in 1926. In 1921 he joined the staff of the Hospital for Diseases of the Throat at Golden Square in London, and he was also consulting surgeon to the ear, nose and throat department at the Westminster Hospital and consultant to the Brompton Hospital and King Edward VII Sanatorium, Midhurst. Despite an extensive private practice, Ormerod was always primarily interested in the academic side of his specialty, and after the formation of the Royal National Throat, Nose and Ear Hospital (in which he played a leading part) he was largely responsible for the creation and inauguration of the Institute of Laryngology and Otology of the British Postgraduate Medical Federation.

When the first, and still the only, chair of laryngology and otology in the United Kingdom was established by the University of London in 1949, he was the natural choice for the appointment. It was fortunate for otolaryngology that Ormerod was willing to relinquish his consultant appointments and private practice to accept this challenge. He built up at the institute a highly successful clinical and research unit. At various times he occupied official positions in the sections of otology and laryngology in the Royal Society of Medicine. Not only was he a co-founder, but also served as secretary of the British Association of Otolaryngologists, and just before his appointment to the professorship he became scientific secretary to the fourth International Congress of Otolaryngology held in London. As a member of the Court of Examiners of the Royal College of Surgeons of England, he was able to influence the training of young otolaryngologists, and the establishment of organized training programmes for these surgeons occupied much of his time. His knowledge of European otolaryngologists, both past and present, made him an invaluable source of reference for intending travellers overseas. In 1953 he gave the Semon Lecture of the University of London, and in 1965 the James Yearsley Lecture. At one time or another he had lectured in most countries of the world, and although not gifted with natural eloquence these communications were so well prepared and constructed that he enjoyed an international reputation as a speaker.

His book *Tuberculosis of the Upper Respiratory Tract* was published in 1939, but his main interest lay in the management of malignant diseases of the head and neck. With his retirement from clinical work in 1959, he was appointed director of research and this permitted him to develop interests in the physiology of the endolymph and pathology of congenital deafness. Several important papers were written on these subjects. When he retired from the Institute of Laryngology and Otology in 1962, he continued to assemble a historic collection of instruments and photographs illustrating the development of otorhinolaryngology. This was dear to his heart and there was nobody living more fitted to accomplish the task successfully. Unfortunately he died before it was completed, but it will be continued by others and will serve as a unique memorial to an exceptional man.

# Helium Deficiency in Old Halo B Stars

by

G. S. GREENSTEIN

Department of Physics, Yale University,  
New Haven, Connecticut

J. W. TRURAN

Institute for Space Studies,  
Goddard Space Flight Center,  
National Aeronautics and Space Administration,  
New York

A. G. W. CAMERON

Belfer Graduate School of Science,  
Yeshiva University, New York, and  
Institute for Space Studies,  
Goddard Space Flight Center,  
National Aeronautics and Space Administration,  
New York

Calculations show that in old halo B stars most helium will have diffused below the photosphere and therefore will not be detected spectroscopically. This may account for the low abundances of helium observed in these stars.

THERE is a growing body of evidence<sup>1-4</sup>, based on a weakness or absence of helium absorption lines in the spectra, for an abnormally low abundance of helium in the atmospheres of old halo B stars. A possible conclusion is that these stars contain little or no helium. If so, these are the only objects we know in which the abundance of helium differs significantly from a more or less universal value of about 25 to 30 per cent by mass<sup>5</sup>.

The large magnitude of this universal abundance is difficult to obtain on the basis of the conventional theory of stellar nucleosynthesis<sup>6,7</sup>. The galaxy would have to have been far brighter for long periods of time than it is now, or than we believe it could have been in the past. Furthermore this abundance also appears to be characteristic of other galaxies which have had significantly different evolutionary histories. One possible explanation for this difficulty is that helium has been produced as a natural consequence of the high temperature-high density phase of an expanding cosmology (ref. 7 and personal communication, R. V. Wagoner, W. A. Fowler, and F. Hoyle). We have attempted to account for both the value of the helium abundance and the likelihood that it is a universal abundance on this basis. The recent discovery of the isotropic microwave background radiation by Penzias and Wilson<sup>8</sup> and others provides direct evidence that the universe was at one time in such a highly compressed state.

The low abundance of helium in the surfaces of old halo B stars appears to be the only evidence which contradicts this hypothesis. In this note we suggest that these stars have a normal abundance of helium in their interiors, and that the surface helium has diffused below the photosphere.

The equilibrium structure of an ionized stellar atmosphere has been discussed by Parker<sup>9</sup>. For the case of an atmosphere consisting of singly ionized hydrogen and helium a lower layer of helium and an upper layer of hydrogen are formed. The abundances of the two constituents decay exponentially on either side of the boundary between them.

This ultimate equilibrium configuration is almost never reached. In most cases the slow diffusion of helium into the interior of a star is opposed by far more rapid motions which return it to the surface. In most main sequence stars these motions take the form of an outer convection zone, the upper boundary of which lies just below the photosphere, but the halo stars with which we are concerned are B stars, which have no such zones. Main

sequence B stars are rapid rotators<sup>10</sup> ( $\Omega \approx 10\Omega_\odot$ ), and this rotation can generate relatively rapid large scale meridional circulation within them which tends to return helium to their surfaces. The halo stars, however, are horizontal branch B stars, which are known to be slow rotators<sup>4,10</sup> except for a possible exception mentioned in ref. 3. Their slow rotation gives rise to internal currents with velocities which are less than the diffusion velocity of helium by several orders of magnitude.

Sweet<sup>11</sup> has analysed the currents generated by the uniform rotation of a star. He finds

$$v_{\text{circ}} = v(z)LR^5\Omega^2/M^3 \quad \text{cm/sec}$$

Here  $v_{\text{circ}}$  is the circulation velocity, and  $L, R, \Omega$  and  $M$  are the luminosity, radius, angular velocity and mass of the star, measured in units of those of the Sun. Defining

$$z = R(2.5 \times 10^{-15} \rho_c / T_c)^{1/2}$$

where  $\rho_c$  is the central density and  $T_c$  is the central temperature, he finds

$z$	2	5	7
$\frac{v(z)}{(\text{cm/sec})}$	$7 \times 10^{-11}$	$1.5 \times 10^{-9}$	$6.7 \times 10^{-9}$

The diffusion velocity of helium downwards is given approximately by  $v_d = \frac{1}{2}gt_{\text{coll}}$ ;  $g$  is the acceleration of gravity and  $t_{\text{coll}}$  is the mean time between collisions with other particles. Spitzer<sup>12</sup> has analysed the collision problem for a variety of circumstances: for the cases with which we are dealing

$$t_{\text{coll}} = 7T^{3/2}n_H \text{ sec}$$

Here  $T$  is the temperature in °K and  $n_H$  the number density of hydrogen ions.

In the Sun we have<sup>10</sup>  $T = 6,000$  °K and  $g = 3 \times 10^4$  cm/sec<sup>2</sup>. From this the hydrogen scale height is  $H = 160$  km. We estimate the hydrogen density  $n_H$  at the photosphere by putting the optical depth there equal to unity: that is,  $\tau = (\text{opacity}) (\text{scale height}) (\text{density at photosphere}) = 1$ . The opacity is a function of  $T$  and  $n_H$  (ref. 13); a consistent choice is  $n_H = 10^{17}$  particles/cm<sup>3</sup>. From this we find the diffusion velocity of helium to be  $v_{\text{diff}} = 5 \times 10^{-8}$  cm/sec. The central density and temperature of the Sun are given in Allen<sup>10</sup>; we find  $z = 9$  is that

the circulation velocity caused by the Sun's rotation  $v_{\text{circ}} = 8 \times 10^{-9}$  cm/sec. This is slower than the diffusion velocity. The Sun, however, has an outer convection zone, with large scale motions of the order of magnitude of kilometres per second, which keeps the helium from settling below the photosphere.

In a main sequence *B* star there is no outer convection zone, so the only motion that would oppose the diffusion is a rotation-induced circulation. If we adopt a model where  $M=10$ ,  $L=10^4$ ,  $R=10$ ,  $\Omega=10$  and  $T=3 \times 10^4$  °K at the surface<sup>10</sup>, we find the acceleration of gravity at the surface to be  $g=GM/R^2=3 \times 10^3$  cm/sec<sup>2</sup>. The scale height  $H$  is then 8,000 km and a surface density of  $10^{15}$  particles/cm<sup>3</sup> satisfies the surface opacity condition. We then find that the diffusion velocity is  $5 \times 10^{-5}$  cm/sec. Estimates<sup>10</sup> of central conditions are  $\rho_c=(1/10)\rho_{\odot}$ ,  $T_c=2T_{\odot}$  so that  $z=20$ . Sweet's calculations do not include such large values of  $z$ , but we may estimate an order of magnitude of  $v(z)=10^{-7 \pm 2}$  cm/sec. The circulation velocity then would be  $v_{\text{circ}}=10^{1 \pm 2}$  cm/sec, which is far larger than  $v_{\text{diff}}$ . With velocities of this magnitude, however, material is transported from the centre to the surface of the star in a time short compared with its time scale for evolution. In these circumstances Sweet's results are not applicable. Roxburgh<sup>14</sup> has obtained stable models of such rapidly rotating stars with no meridional circulation at all. These models correspond to a particular distribution of angular rotation with depth within the star: any other velocity field gives rise to circulation. No circulating models have been obtained, however, and it is possible that they are all unstable and evolve into circulation-free states. At present we are unable to say whether a particular rapidly rotating main sequence *B* star possesses meridional circulation or not. We may calculate, however, the minimum circulation which would oppose the helium diffusion:  $v_{\text{circ}}=5 \times 10^{-5}$  cm/sec. This circulation moves material from the centre to the surface of the star in  $7 \times 10^8$  years, which is long compared with the lifetime of the star on the main sequence.

It has recently been found (ref. 15 and T. S. Deeming and G. A. H. Walker, personal communication) that there is a correlation between the strength of helium absorption lines in main sequence *O* and *B* stars and their projected angular velocity. The same effect is observed in *Be* stars which are all presumably rotating at the verge of equatorial rotational instability. Such stars presumably bring helium to the surface near the equator, and diffusion may be responsible for weakening the helium lines near the poles.

The halo stars of interest here are horizontal branch *B* stars. They have no outer convection zones. They are thought to have evolved from stars similar to the Sun, through a red giant stage, to their present state. During the red giant stage they would have lost some fraction of their masses and a large fraction of their angular momentum. Thus if we take  $M=1$ ,  $L=10^3$ ,  $\Omega=1$  and  $T=3 \times 10^4$  °K we over-estimate their circulation velocities. Sargent and Searle<sup>3</sup> measure the surface gravity of their peculiar stars to be about  $g=5 \times 10^5$  cm/sec<sup>2</sup>. Setting  $g=GM/R^2$  we find  $R=0.25 R_{\odot}$ . As before we find the scale height=50 km, the surface density to be  $10^{16}$  particles/cm<sup>3</sup> and the diffusion velocity of helium to be  $v_d=10^{-3}$  cm/sec. The helium diffuses downwards one scale height in a time far less than the time during which the star remains on the horizontal branch.

We encounter a difficulty in applying Sweet's results directly to this star, because his calculations refer to a point-convective stellar model. Horizontal branch stars possess a dense helium core containing perhaps three-quarters of the star's mass but occupying a small fraction of its volume. Within this core  $\rho_c=10^4$  g/cm<sup>3</sup>,  $T_c=10^8$  °K. If we calculate  $z$  from these parameters we find  $z=2 \times 10^4$ —a ridiculously large value—but the helium core does not participate in the circulation currents, and should properly be excluded in some way from the problem.

We may approximate the actual situation by estimating the conditions just outside the core.

We estimate  $\frac{T_c}{T_{\odot}} = \frac{R_{\odot}}{R}$  since for homologous contrac-

tion of a star,  $TR=\text{const}$ . Approximately  $4\pi\rho_c R^3/3=\text{mass}$ ; we find  $\rho_c R^3 M_{\odot}/M = \rho_{\odot} R_{\odot}^3$ . If we assume that the mass outside the core is quarter the star's mass, and it is distributed through a volume comparable with that of the star, we find

$$\rho_c = \frac{\rho_{\odot}}{4} \left( \frac{R_{\odot}}{R} \right)^3$$

From these  $z=z_{\odot}/2$  and  $v_{\text{circ}}=2 \times 10^{-10}$  cm/sec. This circulation velocity must be increased near the stellar surface to take into account continuity of flow. Mestel<sup>16</sup> has pointed out that Sweet's results need modification; in a uniformly rotating star a critical level surface is formed at which the meridional circulation vanishes, and outside which the meridional circulation is greater than that in the interior by a factor  $\rho^*/\rho$ , where  $\rho^*$  is the density at the critical surface. According to Mestel,

$$\frac{\rho^*}{\rho} = \frac{2}{3} \frac{\Omega^2 R^3}{GM}$$

where  $\bar{\rho}$  is the mean density and c.g.s. units are employed throughout the above expression. With the parameters assumed above for the horizontal branch *B* star, we find finally that  $v_{\text{circ}} \sim 10^{-5}$  to  $10^{-6}$  cm/sec. This is several orders of magnitude slower than the downward diffusion velocity.

The only other motion which could counteract the downward diffusion of helium would be the presence of a stellar wind, in which the atmospheric layers would be subject to hydrodynamic expansion away from the star. In general such expansion would require the presence of a hot corona, and the heating of the corona requires the generation of waves by turbulence or vibration in the outer convection zone. Because these motions appear not to be present in the horizontal branch *B* stars, no significant stellar wind should be present.

Supergiant *B* stars appear to be losing mass at a rapid rate (D. C. Morton, personal communication). It has been proposed (L. Lucy and P. M. Solomon, personal communication) that this loss of mass arises from the radiation pressure on certain ions in certain stages of ionization, where strong resonance lines lie near the peak of the Planck spectrum. Main sequence *B* stars do not show this effect (D. C. Morton, personal communication), and the lower luminosity to gravity ratio in the horizontal branch *B* stars should assure that the process will not be important in them.

From these considerations we see that the horizontal branch *B* stars are the only general class of star in which it can be expected that helium will gravitationally settle out of the photosphere. If the main sequence *B* stars were to rotate more slowly, we would expect some gravitational settling to take place; we have noted that some sharp-lined main sequence *B* stars have weak helium lines<sup>15</sup>. Thus we conclude that the horizontal branch *B* stars should not be considered evidence against the cosmological synthesis of helium.

Similar diffusion arguments hold with respect to other ionic species. Most of the abundant lighter elements will be singly or doubly ionized in *B* star photospheres. The diffusion velocity of an ion of mass  $m$  and charge  $Z_{\text{eff}}$  is proportional to the quantity  $m^{1/2}/Z_{\text{eff}}^2 [\Phi(x) - G(x)]$ , where the function  $[\Phi(x) - G(x)]$  is tabulated in ref. 12. In horizontal branch *B* stars typical light and medium elements diffuse downwards in the range 1–10 times faster than helium. In this connexion it may be noted that the star Feige 65 shows abnormally weak lines of oxygen

II, carbon II, nitrogen II, silicon II (absent), and silicon III (ref. 3). If, however, some of these elements possess very strong absorption lines near the peak of the Planck spectrum (L. Lucy and P. M. Solomon, personal communication), then radiation pressure forces may be stronger than gravity, and these elements can then diffuse away from the star.

We thank J. L. Greenstein, I. Iben, R. Schwartz, P. M. Solomon, N. Woolf, and R. J. Tayler for providing very useful comments on the initial draft. As a result we have incorporated additional material into this communication and we are grateful for permission to quote a number of unpublished results.

This research has been supported in part by grants from the National Aeronautics and Space Administration. One of us (J. W. T.) holds a research associateship at the Institute for Space Studies.

## Uranium and Thorium Abundances in Carbonaceous Chondrites

by

J. W. MORGAN

J. F. LOVERING

Department of Geophysics and Geochemistry,  
Australian National University, Canberra

Determinations of uranium and thorium in carbonaceous chondrites by neutron activation show that both uranium and thorium are inhomogeneously distributed within Type I and are generally homogeneously distributed within Type II carbonaceous chondrites. If Type I carbonaceous chondrites represent primitive solar material, then for the experimentally determined values of the ratio  $^{232}\text{Th}/^{238}\text{U}$  either a continuous or sudden model of nucleosynthesis is plausible. The value of this ratio does, however, raise some problems.

UNTIL quite recently it was considered that the chondritic abundances of uranium<sup>1</sup> and thorium<sup>2</sup> were constant at about 0.01 p.p.m. and 0.04 p.p.m. respectively. This conclusion was based on the analysis of specimens from the two "ordinary" chondrite classes. More recently, analyses have been reported<sup>3-5</sup> for uranium and thorium in a few samples of Type I and Type II carbonaceous chondrites, the results of which are summarized in Table 1. The carbonaceous chondrites, though rare in occurrence, are generally thought to be of considerable importance because they appear to be more representative of the chemical composition of primitive solar material than any other chondritic class<sup>6,7</sup>. Except for one duplicate analysis of Orgueil<sup>3</sup>, the abundances shown in Table 1 for uranium and thorium are considerably higher than those accepted for the ordinary chondrites. If this difference were real it could be of great significance, because solar abundances calculated from nucleosynthetic theory<sup>8,9</sup> are also much higher than the ordinary chondrite values.

It can be seen from Table 1 that the only case in which it is possible to derive a thorium/uranium weight ratio yields a value of 2.68, equivalent to a  $^{232}\text{Th}/^{238}\text{U}$  atomic ratio of 2.77. Fowler and Hoyle<sup>10</sup> estimated a  $^{232}\text{Th}/^{238}\text{U}$  ratio of 3.8 for primitive solar material, and used this value in conjunction with calculated uranium and thorium nucleosynthetic production rate ratios to show that nucleosynthesis was a continuous process. If, however, the experimentally derived ratio of  $^{232}\text{Th}/^{238}\text{U}$  for Orgueil is used for the same calculation, production of uranium and thorium by a single event some  $6 \times 10^9$  yr ago is indicated<sup>11</sup>. It was therefore of considerable importance that careful measurements should be made for uranium and thorium on as many carbonaceous chondrites as possible.

For this work we accumulated a collection of nine samples of the four known Type I carbonaceous chondrite falls and eight samples of six Type II carbonaceous chondrites. These samples are listed in Table 2. The results for two of the samples (Orgueil IIIc and Renazzo I) were rejected because of suspected contamination of the original samples.

Analyses were made for uranium and thorium by neutron activation. Samples and standards were each sealed in silica ampoules and irradiated together in a graphite facility in the HIFAR reactor at the Australian Atomic Energy Commission Research Establishment at Lucas Heights. The duration of irradiation was usually one week, in a nominal thermal flux of  $9 \times 10^{12}$  neutrons.  $\text{cm}^{-2}.\text{sec}^{-1}$ . Determinations were based on the activities of protactinium-233 and neptunium-239, which were produced by neutron capture followed by beta decay from thorium-232 and uranium-238 respectively. Details of the analytical procedure and discussion of possible sources of interferences have been published previously<sup>12</sup>.

Table 2. SOURCE AND SAMPLING DETAILS OF TYPE I AND TYPE II CARBONACEOUS CHONDRITE SPECIMENS

Meteorite	Sampling details	Weight sample crushed (g)	Source
Type I			
Alais	Small fragments, hand picked	0.176	Prof. J. Orcel, Natural History Museum, Paris
Ivuna I	Coarse powder	2	Dr. L. P. Greenland, U.S. Geological Survey, Washington, D.C.
Ivuna II	Sawn slice from interior	0.311	The Commissioner, Mineral Resources Division, Tanzania
Ivuna III	One small fragment	0.125	Dr. B. Mason, American Museum of Natural History, New York
Orgueil I A	Numerous large fragments	10	Mr. E. O. Chalmers, Australian Museum (specimen No. DR 883), Sydney—originally from Natural History Museum, Paris
Orgueil I B	Three large fragments	1	Prof. W. D. Ehmann, University of Kentucky—originally from British Museum (Natural History) (No. 1960, 331)
Orgueil II	Powder	0.531	Kyancutta Museum, South Australia—originally from Natural History Museum, Paris
Orgueil III C	Small fragments, hand picked	0.294	Dr. L. P. Greenland, U.S. Geological Survey, Washington, D.C.
Orgueil IV	Small fragments, hand picked	0.114	Dr. M. V. N. Murthy, Geological Survey of India, Calcutta (specimen No. 255)
Tonk	Small fragments (total 0.281 g), hand picked		
Type II			
Cold Bokkeveld	Several fragments	0.5	Kyancutta Museum, South Australia—originally from Geological Survey of India, Calcutta (specimen No. 141)
Mighei	Fragments broken off sawn slice	0.5	Kyancutta Museum, South Australia—originally from British Museum (specimen No. 1920, 322)
Murray	Fragments broken off larger pieces (6.6 g)	0.5	Dr. E. P. Henderson, National Museum, Washington, D.C. (specimen No. 1769-73)
Nawapali	Small fragments (total 0.5 g)	0.193	Dr. M. V. N. Murthy, Geological Survey of India, Calcutta
Renazzo I	Small fragments (mainly chondrules)	0.2	Dr. B. Mason, American Museum of Natural History, New York
Renazzo II	One fragment	0.630	Dr. E. P. Henderson, U.S. National Museum, Washington, D.C.
Renazzo III	Sawn slice, cleaned	0.337	Prof. P. Gallitelli, University of Bologna, Italy
Staroe Boriskino	Several fragments (total 0.40 g)	0.30	Dr. E. L. Krlnov, Committee on Meteorites, U.S.S.R. Academy of Sciences, Moscow

Schmitt (personal communication) has suggested a possible source of error in the analytical procedure for neptunium-239. His chief doubt appears to be concerned with the possibility that fission products, particularly cerium, are not completely removed by the method. This seems extremely unlikely, however, because the procedures used are actually based on well established methods for the separation of neptunium from fission product mixtures. The decontamination factor for cerium is particularly good, probably between  $10^6$  and  $10^8$ .

The results for the analyses are shown in Table 3. Included for completeness are the results for Orgueil I A which have been published previously<sup>5</sup>.

*Type I carbonaceous chondrites.* Comparison of the Orgueil results in Table 3 with those previously reported and summarized in Table 1 indicates that the large discrepancy in uranium abundances found in earlier work is caused by the extreme inhomogeneity of the distribution of uranium and thorium in the Orgueil fall. It is clear that the results for Orgueil I A are truly representative of this specimen of the meteorite fall, as values obtained from Orgueil I B are almost identical, even though the second sample was prepared from three large lumps from the same bottle, and was not a further split of the same powder. Similarly the Orgueil uranium values previously

reported by Reed *et al.*<sup>3</sup> are very similar to those from Orgueil IV analysed here. The results for Orgueil II show intermediate values for uranium and thorium.

It will be seen that for Ivuna also there is a large variation in uranium values, the highest being almost twice as great as the lowest. Thorium values, on the other hand, are remarkably constant. The results for the other two falls, Tonk and Alais, lie well within the range of values defined by Orgueil and Ivuna.

*Type II carbonaceous chondrites.* The uranium results obtained here for Mighei and Murray agree well with those of previous workers. The Mighei value reported by Reed *et al.*<sup>3</sup> was a single determination and is identical with the lower of the values reported here. Goles and Anders made duplicate determinations on Mighei, and the results of the present work lie well within the range of their two values. The new results for Murray are only about half as large as the average of the triplicate analysis by Goles and Anders<sup>4</sup>, but the lowest of their results does not differ significantly from the results reported here.

To discuss the abundances in different chondrite classes, and to compare them with calculated solar abundances, it is necessary to convert analytical results to atomic abundances. By convention it is customary to normalize to  $10^6$  silicon atoms. Greenland and Lovering<sup>13</sup> have suggested that it may be preferable to normalize to titanium, especially when comparing observed abundances in the Sun's photosphere with chondritic abundances. This innovation, however, has not been generally adopted and in this paper normalization will be with reference to silicon. Atomic abundances calculated in this way are shown in Table 4.

In order to calculate mean abundances as fairly as possible, each meteorite fall was given unit weight. Results for the single samples of Alais and Tonk were therefore given unit weight; each sample of Ivuna was given one third weight, and for Orgueil, samples II and IV were given one third weight and I A and I B one sixth weight. All the Type II samples were given unit weight, except for Renazzo, where each of the two samples was given one half weight.

These weighted means are shown at the bottom of Table 4. A *t* test of the two sets of means showed that they were not significantly different at the 95 per cent confidence level. The weighted data for the two groups were therefore combined to give mean abundances for all the carbonaceous chondrites.

It is interesting to compare these empirical uranium and thorium abundances with those calculated from theories of nucleosynthesis. The abundances of thorium-232, uranium-235 and uranium-238 change with time as all three nuclides are subject to radioactive decay. For

the calculation of solar abundances it is therefore necessary to establish a time scale for the production of these nuclei, as well as estimating relative production rates. Burbidge *et al.*<sup>14</sup> proposed a nucleosynthesis model in which uranium and thorium are formed from seed nuclei of the iron group elements by neutron capture at a rapid rate compared with intervening decays (the so-called *r* process). They were able to calculate relative production rates for uranium-235 and uranium-238, and from the known present day isotopic ratio of these two nuclides they derived several cosmochronological models based on the differential radioactive decay rate. The rate of production of thorium-232 was also calculated, but at that time the present day  $^{232}\text{Th}/^{238}\text{U}$  ratio for the solar system was considered to be very uncertain, and independent confirmation of their chronologies by using the differential decay of thorium-232 and uranium-238 was not attempted.

Fowler and Hoyle<sup>10</sup> re-examined the production of uranium and thorium by the *r* process. From terrestrial lead isotope measurements<sup>15</sup> and direct determinations of meteoritic uranium and thorium abundances<sup>1,2</sup>, they estimated a value of  $3.8 \pm 0.3$  for the present day solar  $^{232}\text{Th}/^{238}\text{U}$  ratio. Using the differential decay rates of thorium-232 and uranium-235 relative to uranium-238, it was found that a concordant solution suggested a model in which nucleosynthesis was continuous. In this model *r* process nucleosynthesis began  $11.6 \times 10^9$  yr ago, and has decreased exponentially until at present it is taking place at only 26 per cent of its original rate. The solar system was isolated from nucleosynthetic sources about  $4.7 \times 10^9$  yr ago.

If the  $^{232}\text{Th}/^{238}\text{U}$  ratio in the carbonaceous chondrites is representative of that of primitive solar material, the results of the present work are not in conflict with the Fowler-Hoyle chronology. Unfortunately the uncertainty of the experimental ratio is so large as to permit also a concordant solution for sudden synthesis. The continuous model of nucleosynthesis is so widely accepted for abundance calculations, however, that it will be used in the following discussion. Hoyle and Fowler<sup>8</sup> used their own cosmochronological model to calculate the atomic abundances of uranium and thorium in primitive solar material. In order to relate abundances to silicon (which is not formed by the *r* process), it was necessary to estimate a normalizing factor,  $r'$ , for uranium, thorium and their progenitors. Because they believed that values for this factor of  $> 0.4$  and  $< 0.2$  were unlikely, Hoyle and Fowler adopted  $r' = 0.3 \pm 0.1$ .

The atomic abundances which they calculated using this factor are shown in Table 5, together with the experimental results of the present study.

Table 5. COMPARISON OF CALCULATED AND EXPERIMENTAL SOLAR ABUNDANCES OF URANIUM AND THORIUM

	$r'$	Atomic abundances per $10^6$ silicon atoms	
		Uranium	Thorium
Calculated			
Hoyle and Fowler <sup>8</sup>	0.3 $\pm$ 0.1	0.034 $\pm$ 0.011	0.130 $\pm$ 0.043
Clayton <sup>9</sup> Lead = $2.5 \pm 1.0$	0.42 $\pm$ 0.17	0.048 $\pm$ 0.019	0.184 $\pm$ 0.074

Clayton<sup>9</sup> has also considered the problem of the abundances of uranium and thorium in primitive solar material. From the neutron capture cross-sections of lead-206 and lead-207 he was able to estimate the  $^{206}\text{Pb}/^{207}\text{Pb}$  ratio formed by the *s* process (that is, by neutron capture on a slow time scale compared with that of intervening decays). The primordial lead isotope ratios, exclusive of georadiogenic contributions, have been measured<sup>16</sup> in the troilite phase of iron meteorites, which contain appreciable abundances of lead, but (presumably) negligible amounts of uranium and thorium. Using the Fowler-Hoyle chronology, Clayton was able to calculate the change in the  $^{206}\text{Pb}/^{207}\text{Pb}$  ratio by cosmoradiogenic decay and obtained an expression for the normalization factor,  $r'$ , in terms of the solar abundance of lead.

Helliwell<sup>17</sup> found the solar atomic abundance of lead to be  $2.5 \pm 1.0$ , relative to  $10^6$  silicon atoms. From this Clayton derived  $r' = 0.42$ .

More recently Mutschlechner<sup>18</sup> has redetermined the solar abundance of lead to be 1.35 atoms per  $10^6$  silicon atoms. If this new value is used for the calculation it is found that  $r' = 0.23$ . The uranium and thorium abundances derived from these two values of  $r'$  are shown in Table 5.

It is clear from a comparison of the calculated and experimental uranium and thorium values that a very large and significant discrepancy exists. It can therefore be concluded that either the uranium and thorium abundances in the carbonaceous chondrites do not represent those of primitive solar material; or the calculated abundances are too high, and the normalization factor  $r'$  should be around 0.1, corresponding to a solar lead abundance of about 0.6 atoms per  $10^6$  silicon atoms. It should be noted, however, that the few measurements of lead abundances in Type I and Type II carbonaceous chondrites<sup>3,19</sup> are more in agreement with  $0.2 < r' < 0.4$ .

We thank the donors (see Table 2) who made this work possible. We also thank Professor W. A. Fowler for many useful comments during the course of this study and Professor A. E. Ringwood for critically reading the manuscript. The programme was supported in part by a grant from the Australian Institute of Nuclear Science and Engineering.

# Haemoglobin New York

by  
HELEN M. RANNEY  
ALAN S. JACOBS  
RONALD L. NAGEL

Department of Medicine and the Heredity Unit,  
Albert Einstein College of Medicine, New York

A haemoglobin variant has been found in which a glutamic acid amino-acid residue is substituted at position 113 in the  $\beta$  chain for the usual neutral valine. This haemoglobin is called after the city in which it was found and is Hb- $\beta$ 113 Glu.

MOST of the abnormalities of human haemoglobin (Hb) have been identified on the basis of alterations in electrophoretic mobility of the haemoglobin variants. The present article is concerned with a haemoglobin which was difficult to separate from normal haemoglobin (Hb A) on electrophoresis in starch gels although more clear cut separation was obtained with paper electrophoresis (Figs. 1A and B). The variant haemoglobin, designated haemoglobin New York, migrated slightly further toward the anode at pH 8.6 than did Hb A, but the difference in mobility was less than would be expected from a net difference of two charges which is commonly found in abnormal haemoglobins.

Haemoglobin New York (Hb N.Y.) was encountered in a Chinese-American family in which three individuals were heterozygous for the new variant and two were doubly heterozygous for Hb N.Y. and high  $A_2$  thalassaemia. The interaction with high  $A_2$  thalassaemia, which resulted in the synthesis of large amounts of Hb N.Y. and little or no Hb A, together with the absence of a minor component which would correspond to the  $\alpha_2$  abnormal  $\delta_2^A$  component expected in an  $\alpha$ -chain variant, suggested that Hb N.Y. represented a substitution of the  $\beta$  chain. Hybridization studies were not satisfactory but on electrophoresis of globin on urea gels by the method of Chernoff and Pettit<sup>1</sup> the  $\beta$  chains of Hb N.Y. migrated farther toward the anode than did the globin of Hb  $\beta^A$ , while  $\alpha^{N.Y.}$  chains did not differ in mobility from the normal  $\alpha$  chains.

For structural studies, haemolysates were prepared from the blood of an individual most of whose haemoglobin was of the variant type. Haemoglobin N.Y. was separated from Hb F and from non-haem proteins by column chromatography on 'IRC-50' with developer No. 2 of Allen *et al.*<sup>2</sup>, and was later isolated by starch granule electrophoresis in veronal buffer pH 8.6. To minimize possible contamination with Hb A, only the more rapidly migrating portion of the main component was eluted from the starch granule separation. Peptide maps prepared by the method of Baglioni<sup>3</sup> from the tryptic digest of globin of Hb N.Y. did not reveal significant differences from maps of globin of Hb A.

The  $\beta$  chains of Hb N.Y. and of Hb A were isolated by a modification of the method of Bucci and Fronticelli<sup>4</sup> in which the haemoglobin was exposed to parahydroxymercuribenzoate (PMB) at pH 5.8 overnight and  $\beta$  polypeptide chains (with —SH groups blocked by PMB) of Hb N.Y. and of Hb A were isolated by electrophoresis on starch granules in barbital buffer at pH 8.6. The  $\beta$  chain component was eluted, concentrated by ultra-filtration and the respective globins were prepared by precipitation with acid-acetone. A sample of each lyophilized globin was treated with mercaptoethanol, urea and, after dialysis,

with ethylenimine by the method of Clegg, Naughton and Weatherall<sup>5</sup>. The conversion by ethylenimine of cysteine residues to *S*-aminoethyl-cysteine results in a modified

Fig. 1. A, Filter paper electrophoretic pattern. Tris-EDTA-borate-veronal buffer pH 8.6. Anode on right. Unstained. Arrow indicates site of application of sample. (1) Hb N.Y. (from individual doubly heterozygous for Hb N.Y. and high  $A_2$  thalassaemia); (2) normal Hb A; (3) Hb A and Hb N.Y. (from individual heterozygous for Hb N.Y.); (4) Hb S + Hb A (from unrelated individual with sickle cell trait). B, Starch gel electrophoresis of haemoglobin from individuals with Hb N.Y. and from a normal individual. Tris-borate buffer pH 8.6. Anode on right. Benzidine stain. Benzidine stain diffused somewhat; consequently resolution was sharper in unstained gels; addition of ethylenediamine tetraacetic acid did not improve the resolution. Sample Ja contained Hbs  $A_2$ , A and N.Y.; sample N from a normal individual contained Hbs  $A_2$  and A; sample Ge (from individual doubly heterozygous for Hb N.Y. and high  $A_2$  thalassaemia) contained increased proportions of Hbs  $A_2$  and F together with Hb N.Y.

globin which no longer contains a trypsin resistant "core"<sup>6,7</sup>. Peptide maps of tryptic digest of aminoethylated (AE)  $\beta^A$  and  $\beta^{N.Y.}$  chains are shown in Fig. 2. Aminoethylated globin New York contained a peptide which differed chromatographically and migrated farther toward the anode than did the corresponding peptide of AE $\beta$  globin A. The differing peptides were eluted by the method of Sanger and Tuppy<sup>8</sup>, hydrolysed in 6 normal hydrochloric acid for 22 h at 105° C, and applied directly<sup>5</sup> to the short and long columns of an automatic amino-acid analyser (Beckman 120B).

In Table 1 are given the results of the amino-acid analysis and the composition of the peptides from AE $\beta^{N.Y.}$  and AE $\beta^A$ .

Table 1. AMINO-ACID ANALYSIS AND COMPOSITION OF PEPTIDES  $\beta$ T-12b FROM AE $\beta$  CHAINS OF Hb N.Y. AND OF Hb A

Amino-acid	AE $\beta^{N.Y.}$			AE $\beta^A$		
	Found ( $\mu$ moles)	Molar ratio	Integral value	Found ( $\mu$ moles)	Molar ratio	Integral value
Lysine	0.139	1.0	1	0.070	0.8	1
Histidine	0.280	2.1	2	0.159	1.9	2
Glutamic acid	0.113	0.8	1	—	—	—
Glycine	0.152	1.1	1	0.107	1.3	1
Alanine	0.120	0.9	1	0.092	1.1	1
Valine	—	—	—	0.083	1.0	1
Leucine	0.134	1.0	1	0.069	0.8	1
Phenylalanine	0.128	1.0	1	0.088	1.1	1

The core peptide of the  $\beta$  chain of composition indicated for the peptide derived from Hb A in Table 1 corresponds to residues 113 to 120 in the  $\beta$  chain sequence<sup>9</sup>:

112 113 114 115 116 117 118 119 120  
Cys - Val - Leu - Ala - His - His - Phe - Gly - Lys

This sequence is the carboxyl terminal part of  $\beta$ T-12: it results from the trypsin attack of the bond between  $\beta$ 113 and  $\beta$ 112 (an *S*-aminoethyl-cysteine residue in AE $\beta$  globin). This basic peptide was found by Jones<sup>7</sup> in AE $\beta$  globin and was designated  $\beta$ T-12b. In Hb N.Y.,  $\beta$ T-12b peptide lacked a valine residue present in Hb A and contained a mole of glutamic acid which was absent from

Hb A. Because the  $\beta$ T-12b peptide of  $\beta^A$  contains only one valyl ( $\beta$ 113) residue in Hb N.Y., valine  $\beta$ 113 appeared to be replaced by glutamic acid. The difference in electrophoretic mobility in the peptides  $\beta$ T-12b of Hb N.Y. and of Hb A strongly suggested that the substituted residue in Hb N.Y. was glutamic acid rather than glutamine, although the absence of glutamine in  $\beta$ T-12b from Hb N.Y. has not been directly demonstrated. Furthermore the substitution of glutamic acid, but not of glutamine, for valine could result from a change in a single base of the triplet code of messenger RNA (ref. 10). Because the substitution of glutamic acid for valine appeared to be at the N-terminal position in the peptide  $\beta$ T-12b, confirmatory evidence for the substitution was obtained by treating these peptides from Hb N.Y. and from Hb A with fluorodinitrobenzene by a modification of the method of Sanger<sup>11</sup>. The peptides were eluted from four peptide maps, exposed to fluorodinitrobenzene, extracted with ether, and the aqueous solutions hydrolysed at 105° C for 12 h. In peptide  $\beta$ T-12b from Hb A, DNP-valine was demonstrated by thin layer chromatography of the ether soluble fraction of the hydrolysate. Direct demonstration of DNP-glutamic acid in  $\beta$ T-12b from Hb N.Y. was not achieved in two attempts; however, on each occasion, the molar ratio of glutamic acid had decreased markedly (to level encountered from contaminants on analyses of paper elutions) on amino-acid analysis of the aqueous phase of the hydrolysate.

The properties conferred on Hb N.Y. by this core substitution are of some interest. The  $\beta$ 113 residue corresponds to the helical residue G15 in the model of Perutz<sup>12</sup>. Residue G15 is apparently at the surface or in a surface crevice of the polypeptide chain<sup>13</sup>; the corresponding residue of the  $\alpha$  chain is threonine, a polar residue. Although G15 is not itself involved in sub-unit contact in tetrameric haemoglobin, nearby residues (G17, G18) are, according to Perutz<sup>12</sup>, possible non-polar contacts between residues in the  $\alpha_1$  and  $\beta_1$  sub-units of haemoglobin. In

Fig. 2. A and B, Peptide maps of AE $\beta$  chains of Hb A (normal) and of Hb N.Y. (kindred 175). Circle indicates site of application. Arrows indicate peptide ( $\beta$ T-12b) in normal Hb which was more negatively charged and differed chromatographically from Hb N.Y. Electrophoresis at 3,000 V for 105 min in 1.25 per cent acetic acid, 1.25 per cent pyridine, pH 4.7. Ascending chromatography for 16 h in pyridine: isoamyl alcohol: water (35:35:27). Papers were cut vertically after electrophoresis (vertical line) in order to fit chromatography tank.

Fig. 1, the electrophoretic mobility of haemoglobin S (in which valine replaces glutamic acid at  $\beta 6$ ) is compared with that of Hb N.Y. (glutamic acid for valine at  $\beta 113$ ). The substituted glutamic residue of Hb N.Y. does not confer the expected charge difference, perhaps because of its location in the tetrameric haemoglobin. The electrophoretic mobilities of isolated  $\beta^{N.Y.}$  globin and  $\beta^A$  globin, which lack the tetrameric conformation, were consistent with an additional 2 net negative charges in Hb N.Y.

The difficulty in demonstrating the heterozygous state for Hb N.Y. on electrophoresis using starch gels or horizontal paper methods makes uncertain the incidence of this variant haemoglobin. Limitations on interpretations of the electrophoretic mobilities of haemoglobins are suggested by the studies of Hb Köln in which substitution of a neutral for a neutral amino-acid residue yielded a haemoglobin with a definite alteration in its electrophoretic mobility<sup>14</sup> and by the present investigation of Hb N.Y. in which the tetrameric haemoglobin containing substitution of an acidic for a neutral amino-acid showed only modest electrophoretic differences from Hb A.

This work was supported by grants from the National Institutes of Health, U.S. Public Health Service. One of us (H. M. R.) is a career scientist of the Health Research Council of New York City. We thank Dr. Olga Blumenfeld for advice and discussion and Mr. James Lampasso for the filter paper electrophoretic patterns.

## Low Molecular Weight RNA Components from KB Cells

by

B. G. FORGET  
S. M. WEISSMAN

Metabolism Branch,  
National Cancer Institute,  
National Institutes of Health,  
Bethesda, Maryland

Simple oligonucleotide maps can be obtained by two-dimensional paper electrophoresis from enzyme digests of 5S RNA from KB carcinoma ribosomes. These maps can be distinguished from those obtained from 5S RNA derived from *E. coli* and from RNA components of low molecular weight derived from KB cells with and without adenovirus infection.

A low molecular weight component of ribonucleic acid (5S RNA) is present, bound to ribosomes, in a number of different cell species: *Escherichia coli*<sup>1,2</sup>, yeast<sup>3</sup>, the aquatic fungus *Blastocladiella emersonii*<sup>4,5</sup>, sea urchins<sup>6</sup>, rat liver cells<sup>6</sup>, KB cells (human epidermoid carcinoma line)<sup>6,7</sup>, and rabbit reticulocytes. Adenovirus 2 infection causes the appearance in KB cells of a somewhat similar RNA component (VA-RNA)<sup>7</sup> which is synthesized at a much greater rate than is 5S RNA in uninfected KB cells. Both VA-RNA and 5S RNA share sedimentation coefficients in sucrose gradients and base compositions which are similar to those of sRNA (soluble or transfer RNA); both can be separated from sRNA by chromatography on columns of methylated albumin kieselguhr (MAK) or on long columns of 'Sephadex G-100'; both differ from sRNA in their inability to accept amino-acids (ref. 6 and Forget, B. G., and Weissman, S. M., unpublished results), and in their lack of methylated bases and pseudouridine. VA-RNA differs from 5S RNA of uninfected KB cells only by small differences in base composition, its rate of synthesis, and its cellular localization predominantly in the 100,000g supernatant fraction of disrupted KB cells. For a lack of more specific distinguishing characteristics these two RNA components were not easily differentiated from each other.

Recently Sanger *et al.*<sup>8</sup> have introduced an improved two dimensional, paper electrophoresis, oligonucleotide mapping technique for the study of enzymatic digests of phosphorus-32 labelled RNA. After electrophoresis, the total number, relative yields, position, and base sequences of the oligonucleotides in an RNA digest give an indication of the size and molecular homogeneity of this RNA

component and can provide a specific "fingerprint" for its identification.

This procedure has enabled us to differentiate definitively from each other: VA-RNA, KB cell 5S RNA, *E. coli* 5S RNA and another 5S-like RNA which we have isolated from ribosomes and nuclei of uninfected KB cells. It has also enabled us to establish the relatively homogeneous nature of these RNA components.

The KB cells, adenovirus 2 stock and techniques of cell culture, inoculation with virus, radioactive labelling, cell fractionation, RNA preparation, fractionation and analysis were the same as previously described<sup>7</sup>, except where otherwise indicated. The KB cell line used (originally obtained from Dr. M. Green) was shown to be free of mycoplasma by culture. *E. coli* cells, type B and strain RNase 19 (RNase deficient)<sup>9</sup>, were obtained from Dr. S. Pestka of the National Institutes of Health; they were grown and labelled as described by Sanger *et al.*<sup>8</sup>.

Between 5 and 10 mc. of (<sup>32</sup>P) phosphoric acid (carrier free, obtained from International Chemical and Nuclear Corporation) was added to 600–1,200 ml. of KB cell suspension cultures: adenovirus 2 infected cells were labelled for 4 h from the 16th to 20th hour after inoculation with virus; uninfected KB cells in a concentration of 2 × 10<sup>6</sup> cells/ml. were labelled for 24–48 h. After disruption of the cells in a homogenizer, the nuclei were removed by centrifugation at 800g and treated as described by Steele *et al.*<sup>10</sup>, to obtain the "nucleolar fraction". The 800g supernatant fraction of the homogenate was made 0.5 per cent with sodium deoxycholate, spun at 10,000g to remove heavier sediment, then the ribosomes and 100,000g supernatant fractions were separated by ultra-

centrifugation for 2 h. The fractionation steps were monitored by light microscopy to ensure (more than 95 per cent) disruption of the cells, removal of cytoplasmic fragments from nuclei, and complete disruption of nuclei with preservation of intact nucleoli. Low molecular weight RNA was prepared from *E. coli* as described by Schleich and Goldstein<sup>11</sup>; after 'Sephadex' gel filtration, the fractions containing 5S RNA ('region or peak 3') were pooled and re-chromatographed on columns of MAK.

After MAK chromatography and analysis for radioactivity, the appropriate RNA fractions were pooled and dialysed for 2 h at 4° C against 2 per cent potassium acetate to remove phosphate. After addition of 0.5 mg of carrier commercial *E. coli* sRNA (Nutritional Biochemicals Corporation) the RNA was precipitated by addition of two volumes of 95 per cent ethanol. Enzyme digestion and oligonucleotide mapping of the phosphorus-32 labelled RNA components were carried out as described by Sanger *et al.*<sup>8</sup>. We used the same materials except for the following: pancreatic ribonuclease, five times crystallized, was obtained from the Sigma Chemical Corp.; ribonuclease *T*<sub>1</sub> from Calbiochem; cellulose acetate strips were obtained from Gelman Instrument Co. ('Cellogel') and from Colab Laboratories, Inc. ('Sephaphore No. 3'). Ethylenediamine tetraacetic acid (EDTA) was added, to a final concentration of 0.01 moles/l., to the buffer in which the strips were soaked before the RNA digest was applied. Gilson model D electrophorators were used for both ionophoresis steps: the temperature of the tanks was maintained at 70° F.

Chromatography on MAK columns of radioactive RNA prepared from *KB* cell ribosomes gave somewhat different results when different extraction procedures were used: when the hot phenol sodium dodecyl sulphate (SDS) technique<sup>12</sup> was used, three radioactive RNA components eluted after sRNA (Fig. 1). These will be referred to here as ribosomal components A, B and C. Occasionally components A and B were not well separated from each other, and formed a single somewhat broader peak. When the cold phenol-SDS technique<sup>13</sup> was used a single main radioactive component, 5S RNA, eluted after sRNA. It was chromatographically similar to the 5S RNA obtained by others<sup>2,6</sup>, and in experiments involving dual label co-chromatography, it occupied the same position as ribosomal component A obtained after extraction with hot phenol-SDS. Much less radioactive material eluted in the positions of ribosomal components B and C when cold phenol-SDS was used to extract the RNA from ribosomes. These patterns were obtained repeatedly from different cell preparations, if the cells were labelled for a relatively long period of time (more than 12 h); the same chromatographic patterns were obtained when the cells were labelled, in non-phosphate deficient medium, with tritiated or carbon-14 uridine. The buffer used for the hot phenol-SDS RNA extractions contained 0.05 per cent bentonite instead of PVS, as used by Scherrer and Darnell<sup>12</sup>.

Fig. 1. MAK column chromatogram of RNA prepared by the hot phenol-SDS method from ribosomes of uninfected *KB* cells labelled for 48 h with 5 mc. of phosphorus-32. Two milligrams of non-radioactive *E. coli* sRNA were added to the RNA preparation before it was loaded on to the column. ○, Absorbance at 260 mμ. ●, C.p.m. phosphorus-32/0.010 ml. of each fraction eluted.

Fig. 2. MAK column chromatogram of RNA prepared by the hot phenol-SDS method from the 'nucleolar fraction' of uninfected *KB* cells labelled for 48 h with 5 mc. of phosphorus-32. Two milligrams of non-radioactive *E. coli* sRNA were added to the RNA preparation before it was loaded on to the column. ○, Absorbance at 260 mμ. ●, C.p.m. phosphorus-32/0.025 ml. of each fraction eluted.

Because 5S RNA ('peak X') has been described in nucleoli of *B. emersonii*<sup>4</sup>, the RNA from the 'nucleolar fraction'<sup>10</sup> of *KB* cells was studied by MAK chromatography after both hot and cold phenol RNA extraction. Chromatography of the RNA gave the same result after either extraction procedure: as with the RNA extracted from ribosomes, three radioactive components (nucleolar components A, B and C) eluted after sRNA (Fig. 2), but the relative amount of radioactivity in each peak was quite different from that obtained with RNA from hot phenol-SDS extracted ribosomes. Table 1 lists the results of alkaline digest base analyses performed on these various RNA components by the method of Sebring and Salzman<sup>14</sup>.

Oligonucleotide mapping was performed on pancreatic ribonuclease digests of the various radioactive RNA components of low molecular weight obtained from ribosomes and nuclei of *KB* cells. Phosphorus-32 labelled 5S RNA extracted from *KB* cell ribosomes with cold phenol-SDS provided, after digestion with pancreatic ribonuclease, a simplified and distinctive oligonucleotide map. A diagram of this map (Fig. 3) is presented with the oligonucleotides numbered according to the scheme of Sanger *et al.*<sup>8</sup>.

Table 1. BASE COMPOSITION OF PHOSPHORUS-32 LABELLED RNA COMPONENTS

RNA species	Cytidylic acid (per cent)	Adenylic acid (per cent)	Guanidylic acid (per cent)	Uridylic acid (per cent)
<i>KB</i> cell				
sRNA	29.9	19.2	30.8	20.1
Ribosomal 16S RNA	27.7	20.6	31.1	20.6
Ribosomal 28S RNA	31.4	18.4	35.4	16.7
5S RNA	27.4	18.8	31.3	22.3
Ribosomal component A	27.3	18.4	32.1	22.2
Ribosomal component B	27.4	18.5	31.9	22.2
Ribosomal component C	27.3	19.6	29.4	23.6
Nucleolar component A	27.4	21.6	29.8	21.2
Nucleolar component B	26.8	20.1	28.1	24.9
Nucleolar component C	24.4	20.1	29.5	25.9
VA-RNA	29.1	18.1	34.4	20.5
<i>E. coli</i> B				
sRNA	27.1	19.2	30.1	23.6
5S RNA	29.3	19.1	34.7	17.0

The radioactive RNA components were isolated by MAK column chromatography (or sucrose density-gradients for ribosomal 16S RNA and 28S RNA), and analysed as described by Sebring and Salzman<sup>14</sup>.

Oligonucleotide maps prepared from pancreatic ribonuclease digests of phosphorus-32 labelled *KB* cell ribosomal RNA components A, B and C extracted with hot phenol-SDS gave the following results: components A and B yielded maps indistinguishable from that of the 5S RNA (Fig. 3). Component A is therefore 5S RNA and component B may be an aggregate of 5S RNA. On the other hand, ribosomal component C yielded a map (Fig. 4) which, although simple, differs from the 5S RNA map in a number of areas: Spots 10, 17, 23 and 29 present in 5S RNA are absent in component C, while spots 8, 22, 25 and 45 are present in component C but absent in 5S RNA; spots 9 and 11, very faint in 5S RNA, are very dark in component C, and the larger oligonucleotides also differ.

Fig. 3. Diagram of the autoradiograph of a two-dimensional fractionation of a pancreatic ribonuclease digest of phosphorus-32 labelled *KB* cell 5S RNA. The oligonucleotides are numbered according to the scheme of Sanger *et al.*<sup>8</sup> and are identified in Table 2. Cyclic nucleotides and trace spots thought to result from random nuclease activity have been omitted from the diagram.

Oligonucleotide maps obtained from pancreatic ribonuclease digests of the nucleolar 5S-like RNA components gave the following results: nucleolar component *A* gave a map indistinguishable from that of 5S RNA, but nucleolar components *B* and *C* both gave maps which closely resembled that of ribosomal component *C*. The latter maps differ from that of ribosomal component *C* by the presence of additional spots: spots 10, 16 and a few other faint spots are present in the nucleolar maps, but not in the ribosomal component *C* maps. On the basis of oligonucleotide maps, therefore, other homogeneous 5S-like RNA components, present in RNA from both ribosomes and the nucleolar fraction of *KB* cells, exist in addition to the principal 5S RNA component of *KB* cell ribosomes.

Oligonucleotide mapping also provided a tool for comparing 5S RNA of *KB* cells with that obtained from bacteria. 5S RNA from *E. coli* cells labelled with phosphorus-32 was digested with pancreatic ribonuclease and mapped in the same fashion as the *KB* cell 5S RNA. The resulting maps (Fig. 5) were identical for both the *B* and RNase 19 (RNase deficient) strains of *E. coli*, but differed from the maps of *KB* cell 5S RNA. The map of *E. coli* 5S RNA reveals a simple pattern, but many of the oligonucleotides present are different from those of *KB* cell 5S RNA: spots 17, 28, 29 and 30 present in *KB* 5S RNA are absent in *E. coli* 5S RNA; spots 35 and 62 prominent in *E. coli* 5S RNA are absent in *KB* 5S RNA. In addition, the larger oligonucleotides differ and spots 2' and 9' representing the ends of the molecule of *E. coli* 5S RNA<sup>15</sup> are absent from *KB* 5S RNA. Spot number 6' probably represents the 5' end of *KB* cell 5S RNA. There are therefore differences in the primary structure of the chief 5S RNA components of these two species, and the presence of 5S RNA in the RNase deficient strain of *E. coli* makes it less likely that 5S RNA results from RNase action on heavier molecular weight RNA components.

Finally, the oligonucleotide maps obtained from pancreatic ribonuclease digests of phosphorus-32 labelled VA-RNA (Fig. 6) were quite different from those of the major *KB* cell or *E. coli* 5S RNA components, or those

of the other *KB* cell 5S-like RNA components. The map was slightly more complex than the 5S RNA maps. It contained more trace spots and these spots were darker than the very faint trace spots obtained on 5S RNA maps. These could result from small amounts of other ribonucleic acids contaminating the VA-RNA preparations or could indicate that VA-RNA is larger and/or less homogeneous than 5S RNA. The VA-RNA map was still simple and distinctive, however, when compared with maps which we obtained from pancreatic ribonuclease digests of *KB* cell sRNA and ribosomal RNA. These maps were extremely complex and similar to those presented by Sanger *et al.*<sup>8</sup> for *E. coli* sRNA and ribosomal RNA. The VA-RNA map differed from the map of the major *KB* cell 5S RNA (Fig. 3) in the following areas: spots 16, 19, 26, 27, 37 and 62 present in VA-RNA are entirely absent in *KB* cell 5S RNA maps; while spots 17, 23 and 24 present in 5S RNA are absent from VA-RNA; spot 11, prominent in VA-RNA, is present only in trace amounts in 5S RNA, whereas spot 10, prominent in 5S RNA, is faint in VA-RNA. Finally, the larger oligonucleotides present in VA-RNA are different from those in the 5S RNA map.

These differences in the composition and proportional yields of oligonucleotides obtained from pancreatic ribonuclease digests of VA-RNA and 5S RNA indicate that these two RNA components contain many regions in their molecules where there are no common base sequences. VA-RNA and 5S RNA are therefore different molecules easily distinguishable one from another by oligonucleotide mapping. Ribonuclease *T*<sub>1</sub> digests of these RNA components also provide distinctive oligonucleotide maps with many differences between VA-RNA, *KB* cell 5S RNA, *E. coli* 5S RNA and the other *KB* cell 5S-like RNA components.

Table 2 lists the base sequences and relative yields of the various oligonucleotides obtained from pancreatic RNase digestion of VA-RNA, *KB* cell 5S RNA, *E. coli* 5S RNA and *KB* cell ribosomal component *C*. There are only twenty-one chief and nine trace components in digests of VA-RNA; twenty-one chief and three trace components

Fig. 4. Diagram of the autoradiograph of a two-dimensional fractionation of a pancreatic ribonuclease digest of phosphorus-32 labelled *KB* cell ribosomal component *C*. The oligonucleotides are numbered according to the scheme of Sanger *et al.*<sup>8</sup> and are identified in Table 2. Cyclic nucleotides and trace spots thought to result from random nuclease activity have been omitted from the diagram.

The oligonucleotides have been numbered according to the scheme of Sanger *et al.*<sup>8</sup>. The 5' end of the oligonucleotide is always given first in the sequence. The exact sequence of the nucleotides between parentheses is not determined. The position of the oligonucleotides is given in Figs. 3-6. C, Cytidylic acid; A, adenylic acid; G, guanylic acid; U, uridylic acid; pUp, uridine di (3'-5') phosphate; ApU, adenylic acid-uridine; pGpU, guanosine di (3'-5') phosphate-uridylic acid; Tr, nucleotides present only in trace amounts.

in digests of KB cell 5S RNA; twenty-one chief and one trace component in digests of *E. coli* 5S RNA; twenty-four chief and one trace component in digests of KB cell ribosomal component C. Certain oligonucleotides are conspicuously absent. The two mononucleotides and four dinucleotides expected are present in substantial amounts in all four components; of the eight trinucleotides possible, one, spot 8 (AAU), is entirely absent from

Fig. 5. Diagram of the autoradiograph of a two-dimensional fractionation of a pancreatic ribonuclease digest of phosphorus-32 labelled *E. coli* 5S RNA. The oligonucleotides are numbered according to the scheme of Sanger *et al.*<sup>8</sup> and are identified in Table 2. Cyclic nucleotides and trace spots thought to result from random nuclease activity have been omitted from the diagram.

Fig. 6. Diagram of the autoradiograph of a two-dimensional fractionation of a pancreatic ribonuclease digest of phosphorus-32 labelled VA-RNA<sup>7</sup>. The oligonucleotides are numbered according to the scheme of Sanger *et al.*<sup>8</sup> and are identified in Table 2. Cyclic nucleotides and trace spots thought to result from random nuclease activity have been omitted from the diagram.

VA-RNA, KB cell and *E. coli* 5S ribonucleic acids but is present in component C which, however, entirely lacks spot 10 (AGU). Several other trinucleotides are present only in trace amounts in one or the other RNA components. Of the sixteen possible tetranucleotides, only two are present in *E. coli* 5S RNA, six in KB cell ribosomal component C, six in KB cell 5S RNA, and seven in VA-RNA. Four possible tetranucleotides (15, 18, 20 and 24) (ref. 8) are entirely absent from all four components. These results have been reproducible in repeated maps of these RNA components obtained from different *E. coli* and KB cell cultures; they characterize VA-RNA, 5S RNA and component C as distinct RNA components and virtually rule out the possibility that they are precursors or random degradation products of ribosomal or messenger RNA or that they result from random aggregation of light weight polynucleotides. The relatively small number of oligonucleotides present constitutes good evidence for the relative homogeneity of these RNA molecules, yet proves that they do not consist of a single repeating sequence.

Although the biological or biochemical functions of VA-RNA and 5S RNA are still unknown, more knowledge of the chemical structure of these low molecular weight components has been obtained by the technique of oligonucleotide mapping. It has demonstrated the relatively homogeneous nature of these molecules, permitted positive differentiation of VA-RNA from 5S RNA and provided evidence for the occurrence of at least two distinct low molecular weight RNA molecules, other than sRNA, in extracts of uninfected KB cells.

After this work was performed, we learned through Information Exchange Group No. 7 (ref. 15) of the work of J. Hindley, M.R.C. Laboratory of Molecular Biology, Cambridge, England. With pancreatic ribonuclease digests of phosphorus-32 labelled 5S RNA from *E. coli* strain MRE-600, he obtained oligonucleotide maps very similar to those which we obtained from 5S RNA of *E. coli* type B and RNase I<sup>9</sup>. By means of acrylamide gel electrophoresis, he was able to separate his chief 5S RNA component into two bands which gave identical maps,

and in addition he was able to isolate from crude preparations of *E. coli* sRNA two other RNA components which, after digestion with enzymes, yielded simple oligonucleotide maps, distinct from that of the chief 5S RNA band. Maps prepared from enzyme digests of yeast 5S RNA also gave a simple pattern, but different from that of *E. coli* 5S RNA and from any of those which we have presented in this article.

We thank Miss Carol Hybner for technical assistance in this work.

Photographs of the autoradiographs can be obtained from us.

## Genetics of Phenylketonuria

by

L. I. WOOLF\*

W. I. CRANSTON†

B. L. GOODWIN\*

Department of the Regius Professor of Medicine,  
Radcliffe Infirmary, Oxford

The first article deals with the problem of using the response to injected phenylalanine to determine whether or not the subject is heterozygous for phenylketonuria. The second article suggests a third allele on the phenylketonuria locus, the corresponding enzyme having a higher affinity for phenylalanine than has the "normal" enzyme.

### Heterozygosity for Phenylketonuria

HETEROZYGOTES for phenylketonuria have only one active gene at the relevant locus, and they may therefore have less phenylalanine hydroxylase in their liver cells than normal people (homozygotes for the wild-type gene). Orally administered loads of phenylalanine are, in fact, metabolized more slowly by heterozygotes than by normals<sup>1-3</sup> and the rise in the concentration of tyrosine in the blood after an oral phenylalanine load is lower in heterozygotes than in normals<sup>4</sup>. These differences are statistically highly significant, but because the absorption of phenylalanine from the gut is a lengthy and variable process it is impossible to calculate rate constants for the metabolism of phenylalanine. Nelson<sup>5</sup> has pointed out that the results obtained could equally well be explained by differences in the distribution of phenylalanine in the various body compartments. The discriminating power of the tests is not very high, and allows a considerable proportion of individuals to be wrongly classified, a most important defect from the practical standpoint. Intravenous loads of phenylalanine have been used (refs. 6-8, and Perry, T. L., personal communication) in efforts to decrease the percentage of people misclassified and produce clearer evidence on enzyme levels. Our experiments and results are described here.

Thirty-one heterozygotes (the parents of children with phenylketonuria) and thirty-four normals (adults unrelated to a phenylketonuric, so far as could be determined) were given phenylalanine as a single dose by intravenous injection of the buffered sodium salt in sterile aqueous solution after an overnight fast. The dose was about 80 mg phenylalanine/kg body weight; 10 mg phenazone/kg body weight was added to the solution for injection. Full details of the mode of administration, etc., will be published elsewhere. A specimen of blood was obtained before the injection and, having allowed

50 min for equilibration after the injection, a second blood specimen was taken; further blood specimens were taken at timed intervals for a total of about 225 min. The plasma was analysed for phenylalanine<sup>9</sup>, tyrosine<sup>9,10</sup> and phenazone<sup>11</sup>, using several replicates for each determination.

In all but four of the sixty-five subjects the rate of return of plasma phenylalanine concentration to the fasting level was proportional to the difference between them, that is,

$$\frac{d\phi}{dt} = -k(\phi - \phi_0)$$

where  $\phi$  is phenylalanine concentration at time  $t$ ,  $\phi_0$  is the fasting level and  $k$  is a rate constant varying from individual to individual. The linearity of the relation of  $\log(\phi - \phi_0)$  to  $t$  was established both graphically and from the sums of squares of deviations<sup>12</sup>. By extrapolating back to the concentration at zero time, and from the amount of phenylalanine injected, the apparent volume through which the injected phenylalanine was distributed (the "phenylalanine space",  $v_\phi$ ) was obtained. The rate at which phenylalanine was being metabolized is

$$v_\phi \cdot \frac{d\phi}{dt} = -k(\phi - \phi_0) \cdot v_\phi$$

Urinary loss of phenylalanine and of its metabolites phenylpyruvic acid and *o*-hydroxyphenylacetic acid was found to be negligible. Although tyrosine hydroxylase can act on phenylalanine, the reaction is slow. Hence, to a close approximation, all the phenylalanine administered was converted to tyrosine by the action of phenylalanine hydroxylase and the parameter  $k$  should be related to the amount of this enzyme in the liver. Taking the liver mass as proportional to body weight or, more accurately, to total body water,  $v_w$  (determined as the phenazone space<sup>11</sup>)  $kv_\phi/v_w$  should be proportional to the amount of

\* Member of external staff of the Medical Research Council.

† Present address: St. Thomas' Hospital Medical School, London.

phenylalanine hydroxylase in each liver cell. The value of  $kv_p/v_w$  for the thirty-four normal individuals was  $1.035 \pm 0.21 \text{ min}^{-1}$  (mean  $\pm$  standard deviation) and for the thirty-one heterozygotes it was  $0.530 \pm 0.15 \text{ min}^{-1}$ . It would appear from these figures that homozygotes for the wild-type gene have almost exactly twice as much enzyme in each liver cell as heterozygotes.

The phenylalanine space,  $v_p$ , was not in general equal to the phenazone space,  $v_w$ . The value of  $(v_p - v_w)/v_w$  was  $0.297 \pm 0.12$  for normal males ( $n = 17$ ),  $0.171 \pm 0.24$  for normal females ( $n = 17$ ),  $0.041 \pm 0.096$  for male heterozygotes ( $n = 15$ ) and  $-0.078 \pm 0.11$  for female heterozygotes ( $n = 16$ ) (mean  $\pm$  standard deviation in each case). The differences between all these values are statistically significant. A positive value of  $(v_p - v_w)/v_w$  implies that phenylalanine is being concentrated in some tissue or tissues, possibly all, and a negative value implies that the intracellular concentration of phenylalanine is lower than the extracellular concentration for some or all tissues. The transport of phenylalanine into cells is probably independent of transport out of cells, and both are probably carrier-mediated, active processes in the cell membrane. It is not necessary to postulate an effect of genes at the phenylketonuria locus on carrier mechanisms in the cell membrane, independent of the effect on phenylalanine hydroxylase; changes in the cell membrane may be a slowly adaptive response to the higher concentrations of phenylalanine in the plasma of heterozygotes<sup>13</sup>. Preliminary investigations on homozygotes for phenylketonuria suggested that levels of  $(v_p - v_w)/v_w$  are lower than in heterozygotes; there appeared to be a tendency for this ratio to be higher where the value of  $\phi_0$  was lower. The magnitude of the negative values of  $(v_p - v_w)/v_w$  in some heterozygotes and phenylketonurics requires that many tissues, perhaps all, should be involved.

If all cells in the body concentrate or exclude phenylalanine to an equal extent, then, since intracellular water is about 75 per cent of total body water for males and 73 per cent for females, the intracellular concentration of phenylalanine in normal males would be 1.40 times as high as the extracellular concentration. This factor would be 1.23 in normal females, 1.05 in male heterozygotes and 0.89 in female heterozygotes. The apparent values of  $k$  would therefore be too high or too low by these factors (compare ref. 5); the corrected mean values of  $kv_p/v_w$  would be 0.739 for normal males, 0.841 for normal females, 0.502 for male heterozygotes, and 0.592 for female heterozygotes.

For distinguishing between heterozygotes and normals, the discriminatory power<sup>14</sup>,  $D/\bar{S}$ , of  $kv_p/v_w$  (uncorrected) is 2.8; using this test alone, 92 per cent of normals and heterozygotes would be classified correctly. The discriminatory power of  $(v_p - v_w)/v_w$  is 2.37 for males and 1.42 for females. The concentration of phenylalanine in the blood after an overnight fast ( $\phi_0$ ) was in our series (including some additional subjects)  $0.818 \pm 0.19$  ( $n = 40$ ) for normals and  $1.133 \pm 0.23$  ( $n = 39$ ) for heterozygotes, giving a discriminatory power of 1.50. The concentration of tyrosine in the plasma after an overnight fast ( $T_0$ ) in normals was  $1.127 \pm 0.19$  ( $n = 39$ ) and  $1.042 \pm 0.23$  ( $n = 34$ ) in heterozygotes. The rate and extent of the rise in blood tyrosine concentration after phenylalanine injection were significantly different in normals and heterozygotes; we have found the best discriminant on this basis to be

$$[\int_0^t (T - T_0) \cdot dt / \int_0^t (\phi - \phi_0) dt]^{\frac{1}{2}}$$

where  $T$  is the concentration of tyrosine in the plasma at time  $t$ . The discriminatory power between heterozygotes and normals of this function is 4.8 for females and 2.7 for males. Only 0.8 per cent of females would be misclassified by this criterion.

With the help of Dr. A. Barr and Dr. C. E. Phelps, discriminatory analysis is being applied to various func-

tions of  $k$ ,  $v_p$ ,  $v_w$ ,  $\phi_0$  and  $T$  with the object of finding a better discriminant incorporating them all.

We thank the heterozygotes and normals who volunteered to act as subjects. Dr. B. Kirman, Dr. V. A. Cowie, Dr. F. P. Hudson, Professor O. Wolff, Dr. G. Woods, Dr. C. Ounsted, Dr. G. E. Roberts, Dr. V. Smallpeice, Dr. A. C. Fairburn and Dr. W. L. Walker very kindly allowed us to investigate the relatives of patients under their care. We also thank Dr. D. Wade for administering the phenylalanine to many of the subjects and collecting blood specimens, and Dr. J. Stern for help with the many tests carried out at the Fountain Hospital and Queen Mary's Hospital, Carshalton.

### Third Allele at the Phenylalanine Hydroxylase Locus in Man

PHENYLALANINE, administered as an intravenous load, is metabolized by a first order reaction in the majority of heterozygotes for phenylketonuria and homozygotes for the wild-type gene (see preceding article). If  $\phi$  is the phenylalanine concentration in the plasma at time  $t$  and  $\phi_0$  is the fasting level, in thirty-three out of thirty-four normal individuals and in twenty-seven out of thirty-one heterozygotes investigated,  $\log(\phi - \phi_0)$  plotted against  $t$  gave a straight line and  $\phi$  plotted against  $t$  gave a curve convex towards the origin (Figs. 1 and 2) in accordance with first order kinetics. In one heterozygote (case 1),

Fig. 1. Logarithm of the concentration of phenylalanine in the blood plasma, minus the pre-injection concentration, plotted against time after injection for a typical heterozygote (○) and a typical normal homozygote (●) for the wild-type gene.

however, the rate of disappearance of phenylalanine from the blood was linear with time, that is, independent of phenylalanine concentration within the limits studied and obeying zero order kinetics (Figs. 3 and 4).

The mean square deviations from linear regression were calculated for most of the subjects, both normal and heterozygote, and compared with the variance (mean square) due to random error of the determinations (Tables 1 and 2). From Tables 1 and 2 the plot of  $\phi$  against time for case 1 does not depart significantly from linearity, but the plot of  $\log(\phi - \phi_0)$  against time is non-linear. Similarly, in cases 2 and 3, the plot of  $\phi$  against time is more nearly linear than the plot of  $\log(\phi - \phi_0)$  against time (Figs. 3 and 4); in case 2 the deviation from linearity of the arithmetic plot was largely caused by the scattering of points alternately on either side of the best straight line, probably the result of experimental error. In one heterozygote (case 4) it was impossible to decide, either graphically or from the mean square deviations from linear regression, whether first order or zero order kinetics were being followed.

\*H, heterozygote for wild-type and phenylketonuric genes; N, a homozygote for the wild-type gene.

† Variance due to deviation divided by variance due to random error, that is Snedecor's F or 1/F as appropriate.

‡ Probability that the observed deviation from rectilinearity occurred by chance.

§ Deviation from linearity not significant.

There was no detectable qualitative difference between the metabolism of phenylalanine in cases 1-4, the other heterozygotes and normals. The concentration of tyrosine in the blood,  $T$ , rose after injecting phenylalanine into these four heterozygotes, the rate and extent of the rise,

Fig. 2. Concentration of phenylalanine in the blood plotted against time for the same two individuals as in Fig. 1. O, Heterozygote; ●, normal.

Fig. 3. As Fig. 1; cases 1 (+), 2 (O) and 3 (●).

Fig. 4. As Fig. 2; cases 1 (+), 2 (O) and 3 (●).

at the dose of phenylalanine used, being about the same as for the other heterozygotes and

$$\left[ \int_0^t (T - T_0) \cdot dt / \int_0^t (\phi - \phi_0) \cdot dt \right]^{\frac{1}{2}}$$

being within one standard deviation from the mean of all heterozygotes. Urinary excretion of phenylalanine and its metabolites was very similar, in cases 1-4, to that found in the other heterozygotes and in normals.

It is generally assumed, and our results support this view, that the rate-limiting step in the disappearance of phenylalanine from the blood is the conversion of phenylalanine to tyrosine in the liver. Phenylalanine hydroxylase behaves like other enzyme systems in obeying Michaelis-Menten kinetics, that is

$$-\frac{d\phi}{dt} = \frac{\phi V}{K_m + \phi}$$

where  $V$  is the limiting reaction velocity at high substrate concentration and  $K_m$  is the Michaelis constant of the enzyme. In most of the cases we studied, the reaction velocity was proportional to  $\phi - \phi_0$ , that is, the value of  $K_m$  was apparently far higher than  $\phi$ . However, in case 1 and probably in cases 2 and 3, although  $\phi$  was of the same order of magnitude as in the other cases, the reaction velocity was independent of  $\phi$ , that is, the value of  $K_m$  appeared to be well below  $\phi$ .

If, in cases 1-3, the liver cell concentrated phenylalanine to an abnormal extent, so that its concentration in the cytoplasm greatly exceeded  $K_m$ , this might explain our results without invoking an abnormal phenylalanine

Fig. 5. As Fig. 2; case 5.

Fig. 6. As Fig. 1; case 5.

hydroxylase. On the other hand, the distribution of phenylalanine in total body water made any such concentration of phenylalanine by the liver unlikely. The values of  $(v_0 - v_w)/v_w$ , in cases 1-3, who were female, were 0.01, -0.04 and -0.04; these are within one standard

deviation from the mean for female heterozygotes (see preceding article). Equilibration of phenylalanine in the blood with that in tissue fluids was in all cases virtually complete before the first specimen was taken; if equilibration had not been achieved the first point would have been unduly high, exaggerating any convexity towards the origin and giving a result the opposite of that observed in cases 1-3.

These observations could be explained if, in case 1 and perhaps cases 2-4, the rate of transport of phenylalanine into the cells of the liver was the rate-determining step and a zero order process. This requires several additional hypotheses for which there is no evidence.

We conclude that a qualitatively atypical enzyme was probably acting in case 1 and, perhaps, in cases 2 and 3; we further conclude that the single active gene at the relevant locus was, in each case, allelic to both the typical gene and the gene for phenylketonuria.

One "normal" individual gave results different from all the others (Tables 1 and 2, case 5). The plot of  $\phi$  against time gave a smooth curve convex to the origin, but the plot of  $\log \phi$  against time gave a smooth curve concave to the origin (Figs. 5 and 6). The results resemble a combination of those in case 1 and those in a "typical" heterozygote; the deviations from linearity are significantly higher than the random errors of determination on either a logarithmic or arithmetic plot. It seems possible that case 5 possesses both "typical" and "atypical" enzymes and is heterozygous for the wild-type and the third allele described here.

In case 3 a fifth blood sample was taken 51 min after the last of the four required for analysis. The phenylalanine concentration in this specimen was considerably higher than would be predicted by extrapolation of either the logarithmic or the arithmetic curve (Figs. 3 and 4). This could be explained if, as the concentration of phenylalanine fell, it approached  $K_m$  and initially pseudo-zero order kinetics changed towards pseudo-first order kinetics.

The lower  $K_m$  value of the atypical enzyme indicates that phenylalanine has a higher affinity for the atypical than the typical enzyme; the relatively low frequency of the "atypical" allele, at most four out of thirty-one, suggests that possession of an enzyme with increased affinity for phenylalanine does not lead to increased survival fitness.

We thank Dr. M. C. Pike, of the Medical Research Council Statistical Research Unit, for details of the method of calculation of deviations from linearity.

## Fractionation of Beef Liver Ribosomes with Specific Antiserum

by

JOHN A. DUERRE

Guy and Bertha Ireland Research Laboratory,  
Department of Microbiology, School of Medicine,  
University of North Dakota,  
Grand Forks, North Dakota

Ribosomes may be specific in their role in protein biosynthesis. A preliminary study suggests that antisera against specific beef liver proteins selectively precipitate ribosomes to which the specific proteins are bound.

A NUMBER of studies have made it possible to identify the specific proteins associated with bacterial and mammalian ribosomes<sup>1-5</sup>. Some of the ribosomes have been shown to be associated with messenger RNA which appears to bear the nascent proteins<sup>6,7</sup>. The messenger RNA need not, however, be present, as the nascent proteins have been

shown to remain attached to the 70S particles under conditions where most of the messenger RNA is free of the ribosomes<sup>8,9</sup>. Warren and Goldthwait<sup>9</sup> have shown by serological methods that triose phosphate dehydrogenase is associated with a fraction of the total ribosomal population. Similar results have been presented for albumin<sup>5</sup>

and  $\beta$ -galactosidase<sup>8</sup>. The protein RNase does, however, appear to be closely associated with essentially all the ribosomal particles from the pancreas<sup>4</sup>.

In the work presented here antisera against beef liver catalase, albumin and glutamate dehydrogenase were prepared in an attempt to determine whether or not these proteins are bound to the same ribosomes or separate groups of ribosomes.

Beef liver was obtained from a local slaughterhouse. A portion of liver was removed as quickly as possible, sliced and placed directly on ice. The liver was homogenized in five volumes (w/v) of 0.01 molar phosphate buffer, pH 7.4, containing 0.01 molar magnesium chloride and 0.15 normal sodium chloride. The microsomes and ribosomes were prepared according to the procedure of Palade and Siekevitz<sup>9</sup>.

Antisera to catalase, glutamate dehydrogenase and albumin were prepared by immunizing white New Zealand rabbits. The  $\gamma$ -globulin fractions were obtained by ammonium sulphate precipitation and further purified by DEAE-cellulose chromatography<sup>10</sup>.

Catalase was assayed by the method of Beers and Sizer<sup>11</sup> and glutamate dehydrogenase by the methods described by Olson and Anfinsen<sup>12</sup>.

The precipitin curve obtained with varying amounts of catalase and a constant amount of anti-catalase (7.4 mg) is shown in Fig. 1. The amount of  $\gamma$ -globulin necessary for complete precipitation of catalase was calculated to be 43  $\mu$ g of catalase per mg  $\gamma$ -globulin. The catalase-antibody complex retained 100 per cent of the activity of the original enzyme.

The precipitin curve obtained with varying amounts of glutamate dehydrogenase and a constant amount of anti-glutamate dehydrogenase (11 mg) is shown in Fig. 2. Enzyme appeared in the supernatant fluid before the equivalence point was reached. Using the point at which no enzyme was found in the supernatant fluid, the amount of antiserum necessary for complete precipitation was calculated at 17  $\mu$ g of glutamate dehydrogenase for each mg of  $\gamma$ -globulin. The enzyme-antibody complex retained only 15 per cent of the original activity at the point just before the appearance of enzyme in the supernatant fluid. This inhibition appears to be of the steric type, as inhibition decreased from 95 per cent when antibody was present in excess to 75 per cent in antigen excess.

A typical precipitin curve was obtained with varying amounts of albumin and a constant amount of anti-albumin. The amount of  $\gamma$ -globulin necessary for complete precipitation of albumin was 16  $\mu$ g albumin for each mg of anti-albumin.

The beef liver microsomal fraction contained measurable amounts of catalase and glutamate dehydrogenase (Table 1). Treatment with deoxycholate (0.5 per cent w/v) produced particles which were considerably richer

Fig. 1. Quantitative precipitin curve of the reaction between varying amounts of bovine catalase and a constant amount of anti-catalase (7.4 mg). The dashed lines refer to amounts of enzyme recovered in the precipitates and the supernatant fluids.

Fig. 2. Quantitative precipitin curve of the reaction between varying amounts of bovine glutamate dehydrogenase and a constant amount of anti-glutamate dehydrogenase (11 mg). The dashed lines refer to amounts of enzyme recovered in the precipitates and supernatant fluids.

in RNA. After four successive washes, the ribosomes still contained measurable amounts of both enzymes. Crystalline catalase or glutamate dehydrogenase added to the microsomes before treatment with deoxycholate did not affect the enzyme activity of the ribosomes after the second wash.

Table 1. CATALASE AND GLUTAMATE DEHYDROGENASE ASSOCIATED WITH VARIOUS FRACTIONS AFTER SUCCESSIVE CENTRIFUGATION CYCLES

Fraction	Protein: RNA	Catalase (units/mg protein)	Glutamate dehydrogenase (units/mg protein)
Soluble	81	450	89
Microsomal	7.1	27	50
Ribosomal (crude)	1.3	57	21
1 wash	1.4	12	20
2 wash	1.2	10	17
3 wash	1.2	7	16
4 wash	1.2	6	10

Varying amounts of the different antibodies were added to a constant amount of washed ribosomes. The tubes were allowed to stand for 24 h at 4° C. To facilitate the precipitation of the ribosome-antibody complex, anti-rabbit  $\gamma$ -globulin prepared in sheep was added to each tube. The precipitates were collected by centrifugation for 15 min at 3,000g, washed twice, and assayed for RNA, protein and enzyme activity. The amount of anti-catalase or anti-glutamate dehydrogenase necessary for complete precipitation of all catalase or glutamate dehydrogenase activity associated with the ribosomes is given in Table 2. The value listed for anti-albumin is based on the point at which no further increase in RNA precipitate was noted (equivalence zone).

Table 2. PRECIPITATION OF RIBOSOMES\* WITH SPECIFIC ANTIBODIES

$\gamma$ -Globulin fraction	Amount required† (mg)	Protein precipitate (mg)	RNA precipitate (mg)	RNA (%)
Anti-GDH	22	0.66	0.14	0.53
Anti-albumin	11.6	0.49	0.10	0.4
Anti-catalase	7.4	0.54	0.12	0.47
Normal	20	0.16	0.04	0.08

\* 10 ml. ribosomes (26 mg ribosomal RNA) added to each tube.

† Antiserum required for complete precipitation of corresponding antigen.

The amount of ribosomes precipitated with anti-glutamate dehydrogenase was 0.53 per cent of the total RNA. The amount of glutamate dehydrogenase associated with the precipitate was 3–5 units/mg. 90–95 per cent of the catalase activity could be recovered from ribosomes remaining in suspension, and only trace amounts (<1 unit) were associated with the precipitate.

With anti-albumin it was possible to precipitate about 0.4 per cent of the total ribosomal RNA. Detectable amounts of catalase were associated with this precipitate;

on the other hand, 90–95 per cent of both catalase and glutamate dehydrogenase remained associated with the ribosomes remaining in suspension.

The amount of RNA precipitated with anti-catalase was 0.47 per cent of the total added. The amount of enzyme associated with the precipitate was 50–56 units/mg protein; an enrichment of eight to twelve times. The actual number of ribosomes with catalase attached would be somewhat less than 0.47 per cent, because 0.1 per cent of the ribosomes precipitated non-specifically. This non-specific precipitation should not contribute more than 0.1 per cent of the total glutamate dehydrogenase or albumin associated with the total ribosomal population unless these proteins were bound to the same ribosomes. Such a small amount of glutamate dehydrogenase could not be detected in the assay system used, however, because 95–100 per cent of the glutamate dehydrogenase activity was recovered from the ribosomes remaining in suspension, and this enzyme was therefore not bound to the antibody-ribosome complex. The ribosomes remaining in suspension could not be tested directly for albumin, but further addition of anti-albumin after removal of the ribosome-catalase-anti-catalase complex resulted in the precipitation of additional ribosomes.

If the enzymes associated with the ribosomes were the result of contamination with soluble enzymes, no RNA should precipitate unless ribosomes were trapped within the enzyme-antibody-anti-antibody complex. No appreciable increase in the amount of RNA precipitated was found when crystalline catalase or glutamate dehydrogenase, in the amount already present, was added to the

ribosomal suspension before the addition of antibody. Contamination with cytoplasmic elements therefore seems to be negligible as a source of enzyme. Although we cannot rule out the possibility that the protein is adsorbed on to the ribosome, there is evidence that pure enzyme added after homogenization does not increase the enzyme activity associated with the ribosomal fraction after several centrifugation cycles.

In view of these findings, it might be concluded that particular ribosomes are quite specific in their role in protein biosynthesis. Proof of the formation of specific enzymes by specific ribosomes is, however, lacking, in that the ribosomes present at any one time may contain only that enzyme produced by the attachment of specific messenger RNA and only that enzyme which was produced at that particular time would precipitate along with the ribosome.

## Activity of Ribosomal Phosphodiesterase in a Protozoan

by

LAWRENCE H. LAZARUS

OTTO H. SCHERBAUM

Department of Zoology,  
University of California,  
Los Angeles, California

In *Tetrahymena pyriformis* GL a phosphodiesterase bound to ribosomes has a requirement for divalent cations and is stimulated by potassium ions.

THE intracellular ribonuclease of *Tetrahymena* hydrolyses both purine and pyrimidine internucleotide bonds and produces cyclic 2':3'-nucleotides<sup>1</sup> which are slowly converted to nucleotide 3'-phosphates<sup>2</sup>. Three ribonuclease components have been purified several hundred-fold and characterized by their activity on synthetic polyribonucleotides<sup>3,4</sup>. In addition to nuclease activity in the soluble phase of homogenized preparations we found a hitherto undescribed phosphodiesterase activity exclusive to the ribosomal fraction. This phosphodiesterase differs from the soluble ribonuclease in its optimum pH, the effect of cations, and its action on *bis-p*-nitrophenyl phosphate, which is readily hydrolysed by the former but not by the soluble ribonuclease. We report here the distribution of the phosphodiesterase in four cell fractions, the effect of mono- and di-valent cations, and chelating agents on the activity of partially purified enzyme preparation.

*Tetrahymena pyriformis* GL was grown in sterile conditions in a medium containing 1 per cent proteose-peptone, 0.25 per cent yeast extract and 0.1 per cent dextrose. All cultures were aerated and incubated at 29° C. During late log phase the cells were collected,

washed twice in 0.4 per cent sodium chloride and used either immediately or frozen in a bath of alcohol and dry ice and stored at -22° C. All later steps were carried out at the temperature of the ice bath. The washed cells were homogenized by passage through a French press ('Aminco') at 12,000 to 15,000 lb./in.<sup>2</sup>. The homogenate was made 0.05 molar with *tris* hydrochloric acid buffer (pH 7.45) and centrifuged at 2,000g for 10 min. The pellet was washed five times with equal volumes of the *tris* buffer; it will be referred to as "residue". The combined supernatants were centrifuged at 10,000g for 10 min. The second pellet represents the mitochondrial fraction. The supernatant was centrifuged at 105,000g for 90 min. The resulting ribosomal pellet was washed once in *tris* buffer.

The distribution of phosphodiesterase in the *Tetrahymena* fractions is shown in Table 1. Enzyme activity is associated only with particulate fractions, especially the ribosomes. No phosphodiesterase activity was observed in the 105,000g supernatant with incubation of the assay mixture for periods up to 24 h. Although washing of the ribosome fraction in 0.05 molar *tris* hydrochloric acid buffer, pH 7.45, slightly reduced the activity

of phosphodiesterase, washing three times with 0.2 molar *tris* hydrochloric acid buffer, pH 7.45, was sufficient to abolish almost all activity. Using data on total protein in the fractions analysed, the distribution of enzyme activity was calculated, assuming the activity in the crude homogenate to be 100 per cent (right hand column, Table 1). More than 95 per cent of the activity is found in the ribosomal fraction. The ribosome fraction showed a distinct maximum in activity at pH 10.3, but the preparations were also active at lower pH. For example, at pH 5.0 the activity was 30 per cent to 60 per cent of the values at pH 10.3.

Table 1. DISTRIBUTION OF PHOSPHODIESTERASE ACTIVITY IN *Tetrahymena* CELLS

Fraction	Phosphodiesterase activity ( $\mu$ moles/mg/h)	Per cent
Crude homogenate	33.2	100
Residue	0	0
Mitochondria (unwashed)	6.52	4.9
Ribosomes		
Unwashed	139	—
Washed once	125	95.1
Ribosomal wash	0	0
105,000 g supernatant	0	0

The determination of phosphodiesterase activity was carried out in a 1.0 ml. reaction mixture containing 25  $\mu$ moles of diethylamine buffer, pH 10.3, 1  $\mu$ mole magnesium chloride and 1  $\mu$ mole of calcium *bis-p*-nitrophenyl phosphate. The reaction was started by addition of the sample containing 0.5–2.0 mg of protein and terminated by addition of 100  $\mu$ l. of cold 50 per cent trichloroacetic acid after incubation at 29° C for 80 min. After 15 min on ice, the suspension was centrifuged and 0.5 ml. of the supernatant was added to an equal volume of 0.5 normal sodium hydroxide. The absorbancy was determined at 400 m $\mu$ . Each sample was assayed in duplicate and corrected for reaction mixtures without substrate and without protein. The substrate was stable under these assay conditions for several days. The phosphodiesterase activity is expressed in  $\mu$ moles of *p*-nitrophenol formed/mg of protein in the sample.

Using a washed ribosomal fraction in the assay system described in the legend to Table 1, we determined the effect of cations on phosphodiesterase activity in the absence of magnesium. Potassium chloride from 0.2 to 0.8 molar maximally stimulated phosphodiesterase activity on the average of approximately 25 per cent; half as effective (at the same concentrations) were the chloride salts of sodium, as well as lithium and caesium. Ammonium chloride at concentrations of 0.5 moles/l. and 1.0 moles/l. inhibited phosphodiesterase activity 18 per cent and 28 per cent, respectively. An equal concentration of potassium ions completely reversed the inhibition of 0.5 molar ammonium ions.

The divalent cations calcium and magnesium increased phosphodiesterase activity 20 per cent and 7 per cent, respectively, at concentrations of 0.05 moles/l. Calcium was slightly inhibitory at concentrations above 0.5 moles/l. All other cations we tested were inhibitory at a concentration of 0.05 moles/l.; copper ions (13 per cent), ferric ions (95 per cent), zinc ions (100 per cent), cobalt ions (100 per cent) and mercury ions (100 per cent). This effect is caused by cations, because we failed to observe any difference between chloride and sulphate salts using potassium or sodium as the cation. The chelating agents sodium citrate and ethylenediamine tetraacetic acid (EDTA), as well as L-tryptophan<sup>5</sup>, inhibited phosphodiesterase activity (Table 2). The effect of tryptophan was partially reversed by an equimolar concentration of calcium chloride, but not by an excess of potassium chloride (Table 2). This clearly demonstrates that *Tetrahymena* phosphodiesterase requires a divalent cation for activity.

Phosphodiesterase activity has been found in ribosomal fractions prepared from wheat<sup>6</sup>, mammalian tissues<sup>8,9</sup>, milk<sup>10</sup>, *E. coli*<sup>11</sup> and *Lactobacillus casei*<sup>12</sup>. The occurrence of ribosome-bound enzymes *in vivo* has been questioned and the possibility for adsorption artefacts during isolation has been mentioned<sup>13,14</sup>. The inability to dissociate phosphodiesterase activity from *Tetrahymena* ribosomes,

unless the ribosomal structure is disrupted by detergents, indicates that the enzyme is a constituent of the ribosome<sup>4</sup>. This ribosome-bound enzyme with its high pH optimum activity is uniquely distinct from other nucleases in *Tetrahymena*, because both its DNase<sup>15,16</sup> and RNase<sup>3,4,16</sup> have acid pH optima. Furthermore, the highly purified *Tetrahymena* RNase does not hydrolyse *bis-p*-nitrophenyl phosphate<sup>4</sup>.

Table 2. EFFECT OF CHELATING AGENTS ON PHOSPHODIESTERASE ACTIVITY

Additions	$\mu$ moles	Phosphodiesterase activity $\mu$ moles <i>p</i> -nitrophenol	Percentage stimulation	Percentage inhibition
None	—	244	0	0
Sodium citrate	10.0	193	—	19
EDTA	10.0	0	—	100
None	—	137	0	0
Plus potassium chloride	250.0	173	31	—
Plus calcium chloride	10.0	152	10	—
Plus L-(—)-tryptophan	1.0	74.1	—	46
Plus L-(—)-tryptophan	10.0	69.6	—	49
Plus potassium chloride	250.0	86.6	—	50
Plus calcium chloride	10.0	111	—	27

The assay system contained 25  $\mu$ moles of diethylamine buffer, pH 10.3, 2.5  $\mu$ moles of calcium *bis-p*-nitrophenyl phosphate in 1.0 ml. and was carried out as described in the legend to Table 1. The percentage inhibition was calculated using the control for that specific experimental condition, for example, tryptophan plus potassium chloride relative to plus potassium chloride alone.

Monovalent cations are known to stimulate the activity of the phosphodiesterase in *E. coli*<sup>11,17–19</sup>, *L. casei*<sup>12</sup> and snake venom<sup>20</sup>. The stimulation of phosphodiesterase activity by potassium ions and sodium ions could be a non-specific effect of the ionic strength in the reaction mixture. The monovalent cations potassium, lithium, caesium and sodium produced a similar activation of phosphodiesterase independent of the degree of hydration of these ions<sup>21</sup>, and so the observed stimulation suggests some type of direct interaction. The activators may play a part in (a) anchoring the substrate to the enzyme, or (b) stabilizing the enzyme molecule, or (c) increasing the rate of hydrolysis of the enzyme-substrate complex<sup>21</sup>. Because there is an increase in the apparent maximum velocity of the enzyme reaction at a given substrate concentration, possibilities (b) and (c) could apply to a description of the effect of potassium ions on phosphodiesterase activity. The failure to reverse the tryptophan inhibition with potassium ions indicates that this ion is not involved in the binding of enzyme and substrate; the divalent cations of calcium and magnesium could have such a function, because calcium ions partially reverse the inhibition induced by tryptophan (Table 2).

# Origin of Kaposi's Sarcoma from the Reticulo-endothelial System

by

A. D. DAYAN  
Wessex Neurological Centre,  
General Hospital, Southampton

P. D. LEWIS  
Institute of Neurology, London

The histological appearance of Kaposi's sarcoma tissue stained by silver impregnation suggests that the sarcoma originates from the reticulo-endothelial tissue. Like Burkitt's lymphoma, the disease occurs in small areas of Africa, and may be linked with oncogenic viruses.

THE disease variously called "Kaposi's sarcoma" or "multiple idiopathic haemorrhagic sarcoma of Kaposi" has posed many problems to pathologists. Although often regarded as a neoplasm, possibly spreading by metastasis, or perhaps of multicentric origin, it has also been thought of as an infective granuloma and a benign vascular proliferation. There are more than fifty reports of its common occurrence in patients who have, or who later developed, disorders of the reticulo-endothelial system—for example, lymphosarcoma, Hodgkin's disease and leukaemia<sup>1,2</sup>. Because such an association has been noted more often than seems possible for a purely chance occurrence, several authors have suggested that Kaposi's sarcoma is a disease of the reticulo-endothelial system (RES). The only other support for this hypothesis has come from the rather weak circumstantial evidence of the histochemical detection of enzymes in the tumour cells which are commonly found in the RES<sup>3</sup> and the apparent histological continuity of lesions of Kaposi's sarcoma and Hodgkin's disease noted in two patients by Lothe and Murray<sup>4</sup> and Uys and Bennett<sup>5</sup>.

The experimental studies of Marshall<sup>6</sup> showed that certain silver stains used in neuropathology specifically to impregnate microglial phagocytic cells of the central nervous system could be adapted to demonstrate with equal selectivity the majority of cells belonging to the RES elsewhere in the body. We have used Marshall's modification of the Weil-Davenport technique to study the nature of the cells in lesions of Kaposi's sarcoma in five west European patients.

At the London Hospital, from 1908 to 1965, biopsies were taken from five patients with Kaposi's sarcoma, and the histological blocks were still available embedded in paraffin. Sections 20 $\mu$  thick were cut, de-waxed with xylol, hydrated and impregnated with silver by Marshall's<sup>6</sup> modification of the Weil-Davenport technique.

The five patients examined were the only ones with both a clinical and pathological diagnosis of Kaposi's sarcoma who had had skin biopsies and whose paraffin blocks were available. One patient, who had concurrent Hodgkin's disease and Kaposi's sarcoma, had had a biopsy of both a lymph node and a cutaneous lesion. The node showed contiguity of both types of abnormal tissue. This patient is discussed in more detail elsewhere<sup>7</sup>.

The silver impregnation was successful in four of the five cases as shown in Fig. 1 by the characteristic elongated appearance of selectively impregnated normal RES cells scattered throughout the dermis. These cells were far more numerous around Kaposi lesions. In the nodules of Kaposi's sarcoma, many selectively impregnated tumour cells were found wherever conventionally stained sections had shown the characteristic spindle cells massed around proliferating capillaries. The dark brown to black metal-  
lophilic cells measured about 15–20 $\mu$  long by 5–10 $\mu$  in diameter (Fig. 2). They had relatively compact cell bodies from the corners of which short processes could

sometimes be seen to arise (Figs. 3 and 4). The region of the nucleus appeared as a rounded swelling of the cell. They were usually very closely packed together and the crowding prevented full examination of their morphology. Not all cells in the lesions were impregnated, because clear areas were found around foci of inflammatory cells. As reported elsewhere<sup>2</sup>, in our one case where Hodgkin's disease and Kaposi's sarcoma tissue lay next to each other in a lymph node, impregnation of characteristic cells had occurred in both lesions.

Deposition of silver had also occurred on many elongated branching cells in the basal and Malpighian layers of the

Fig. 1. Typically metallophilic cells of the reticulo-endothelial system, probably macrophages, lying near a small blood vessel in the dermis (Weil-Davenport,  $\times c. 120$ ).

Fig. 2. Pyramidal and club-shaped metallophilic cells in Kaposi's sarcoma (Weil-Davenport,  $\times c. 200$ ).

Fig. 3. Selective impregnation of branching cells in Kaposi's sarcoma (Weil-Davenport,  $\times c. 200$ ).

Fig. 4. Metallophilic spindle cells of Kaposi's sarcoma showing their fine processes (Weil-Davenport,  $\times c. 200$ ).

epidermis. On morphological grounds they were identified as melanocytes.

The appearance of the selectively metallophilic cells in lesions of Kaposi's sarcoma is comparable with the results obtained by applying the same method to other normal tissues of the RES. In the present series, normal macrophages were demonstrated in four of the five specimens, and so were the abnormal reticulum cells in the lymph node tissue containing Hodgkin's disease<sup>2</sup>. Published photographs of metallophilic cells in accepted examples of RES disease<sup>6</sup> closely resemble our findings. Marshall's results have been confirmed and extended by several authors in, for example, microgliomata of the brain<sup>7-9</sup>.

Their illustrations are very similar to ours. It must be emphasized that our results are based on wax-embedded material up to 30 years old, and that confirmation is required using freshly fixed tissues for optimal conditions.

We consider that the present results provide strong evidence in favour of Kaposi's sarcoma being a disease derived from the reticulo-endothelial system. Previously, direct support for this suggestion has come only from the high frequency of its clinical association with other accepted disorders of the RES. Histochemical studies<sup>10</sup> have shown several enzymes in Kaposi tissue which are found also in macrophages. In particular, acid phosphatase was present in many tumour cells. The occurrence of this enzyme is not, however, specific for RES cells, and the more primitive types do not always contain it<sup>11</sup>. Electron microscopy of tumour cells<sup>12</sup> has shown multilaminated osmophilic structures in their cytoplasm. They were interpreted as non-myelinated nerve fibres, and this led to a suggestion that Kaposi's sarcoma originates from Schwann cells. Examination of the published photographs does not, however, reveal any axons within the structures; they are too small to be regarded as nerve fibres, and mesaxons are not shown. They probably represent scavenged debris—"myelin figures"—common to many cells under adverse conditions.

If Kaposi's sarcoma is considered as a disease derived from the RES, certain of its other peculiarities become of particular interest. The geographical distribution of the disease is unique in that its highest incidence is in small areas of Africa. In this and other ways it recalls the occurrence and clinical features of another disease of the RES—Burkitt's lymphoma<sup>13,14</sup>. In view of recent reports suggesting the occurrence of oncogenic viruses in Burkitt's lymphoma<sup>14</sup>, it would be interesting to examine Kaposi tissue for the same or related viruses.

We thank Professor I. Doniach and Drs. A. H. E. Marshall and B. Russell for their advice, Mr. H. J. Oliver for performing the silver impregnations, and Mr. R. J. Hunt for the microphotographs.

## Ecology and Taxonomy of the Gorilla

by  
COLIN P. GROVES\*

Unit of Primatology and Human Evolution,  
Royal Free Hospital School of Medicine,  
London, W.C.1

Multivariate analysis shows that the ecological diversity of the gorilla is reflected in the morphology of the skull and is of assistance in subspecific taxonomy.

THE gorilla is the largest living primate, and systematically one of the closest to man. It is probably this closeness as much as anything else that has stimulated a great deal of scientific interest in this animal, from Owen's<sup>1,2</sup>

early osteological studies through the taxonomic era of Matschie<sup>3-6</sup> to the very recent behaviour study of Schaller<sup>7</sup>. The general range of variability is known largely through the work of Schultz<sup>8,9</sup> and the distribution is well known as a result of the work of Coolidge<sup>10</sup> and Schaller.

\* Present address: Department of Anthropology, University of California, Berkeley, California.

It is not clear to what extent gorillas are divided into geographical races—races with ecological determinants—partly because of the typological point of view of the earlier workers and the chance that gorillas tended to be collected in the extreme west and east of the total range of the species. The old literature tends either to describe new forms, based on very little information, or merely to contrast the mountain and lowland types as a whole. Actually, as Schaller has shown, many of the eastern gorillas are at low altitudes. Investigations of the influence of ecology on the morphology of man are only just beginning. It can be supposed, however, that gorillas, lacking the mobility of human beings, are more likely to show a comparatively uncomplex pattern of influence.

A further question which has recently been raised by several authors (Simpson, Mayr, Washburn) is the relationship of the gorilla to the chimpanzee. This question is beyond the scope of the present paper, but is indicative of a new trend of taxonomic thought.

The altitudes at which gorillas are found vary from sea-level in West Africa to 13,000 ft. on the Uganda-Rwanda-Congo border. The whole area of distribution is split into two portions—one in West Africa, approximately between the Nigerian border and the lower Congo River, and one in East-Central Africa, between the Upper Congo River and the Uganda border, being mostly (but not entirely) to the west of the Albertine Rift. These two quite separate geographic regions are generally referred to as the areas of "lowland" and "mountain" gorillas respectively. The currently recognized classification, dating from 1929 (ref. 11), allots a single sub-species to each of these two zones, the western or lowland gorilla being the typical form, *Gorilla gorilla gorilla* Savage and Wyman, 1847, and the eastern or mountain gorilla being known as *Gorilla gorilla beringei* Matschie, 1903. Vogel<sup>12</sup> among others has queried this point of view, basing his judgment on the morphology of the mandible and the frequencies of some non-metrical features.

The first immediately striking feature of this arrangement is that the western gorilla is by no means an exclusive inhabitant of low-lying country: on the plateau of the interior of Cameroun the altitude is around 2,000 ft., while on the Cross River, at the western extreme of the range, altitudes of 5,000 ft. have been recorded for gorillas. Equally, the eastern gorilla is by no means entirely a mountainous form. Schaller<sup>7</sup> shows that at least two-thirds of the eastern distribution area lies in lowland rain forest at altitudes of 1,600–2,600 ft.

For these reasons, it was felt that a new analysis of gorilla material was required, based on as large a number of specimens as possible, with a view to relating geographic variation to ecological factors. The present investigation therefore includes material from all the major collections of the world\*, as well as many minor ones. The five largest collections of the world are located as follows: British Museum (Natural History), London; Powell-Cotton Museum, Quex Park, Birchington, Kent, England; Musée Centrafricaine, Tervuren, Belgium; Institut für spezielle Zoologie und zoologisches Museum, Berlin (East); Natural Science Museum, Cleveland, Ohio, U.S.A. In several other collections there exist a fairly large number of specimens, but these are mostly of unknown locality. In all, including the smaller collections, 469

adult male and 278 adult female skulls were used in this investigation, as well as numerous juveniles which were useful for comparison. The specimens examined included the holotypes of all the many supposed species or sub-species described by Matschie and his contemporaries, with the exception of *Gorilla beringei* Matschie, 1903, and *Gorilla gorilla schwarzi* Fritze, 1912, both of which were destroyed during the war. The original co-types of Savage and Wyman were also examined.

The primary method used was the multivariate technique of generalized distance, which is well described by Trevor<sup>13</sup> and Talbot and Mulhall<sup>14</sup>; the analysis was done by the canonical variates method (see refs. 15 and 16). Although the results of the canonical analysis were of great interest, space precludes their detailed description in the present paper. A total of forty-five measurements was taken on each skull. This large number was reduced by means of correlation coefficients to sixteen, of which ten pertained to the cranium (cranial length and breadth, bi-orbital breadth, palate length and breadth, bi-canine breadth, facial height, post-orbital breadth, tooth row length and nuchal surface height), and six to the mandible (bicondylar and bi-gonial breadths, ramus height and breadth, tooth row length and jaw body breadth). The cranium and mandible were treated separately in the analysis because of a comparative lack of specimens possessing both; thus, there were four analyses to perform because males and females were also taken separately. Taking the smallest geographical units possible (one area or district if there were sufficient specimens, otherwise a fairly circumscribed area) it was possible to use nineteen different groups for the male crania and mandibles, but only eleven for female crania and ten for female mandibles. In each case four of the groups were from the eastern area; the remainder, from the western.

Ecologically the western group can be divided into four sections: (A) Coast, which includes the high rainfall area down the coastal strip in West Africa from the lower Njong River, Cameroun, the mouth of the Congo, and extending inland to the low-lying Mambili River region. (B) Plateau; the lower rainfall area of the Cameroun hinterland, above 2,000 ft.; most of the groups large enough to be used in the analysis were from districts within this area, for example, Batouri, Lomie, Abong Mbang, Ebolowa. (C) Sangha, a zone ecologically intermediate between (A) and (B); on both sides of the Sangha River, from three localities: Youkadouma (includes, for example, Ziendi), Nola and Ouesso. (D) Nigeria, the Cross River district, from 1,000 ft. to nearly 6,000 ft. in hilly country, and rather isolated from the other three. These areas are shown on the map in Fig. 1.

The four eastern groups used in the analysis were, to use Schaller's terminology: Virunga, from 8,000–13,000 ft., in the Virunga Volcanoes; Tshiaberimu, from about 5,000–8,000 ft.; the mountains west of Lake Edward; Mwenga-Fizi, of similar altitude but less precipitous topographically; it is west of the north end of Lake Tanganyika; Utu, lowland rain forest west of the mountainous region, averaging 2,000 ft. high.

The generalized distance analysis shows that this ecological diversity is reflected in morphological diversity (Table 1). At first all nineteen groups (or eleven, or ten, according to which section of the analysis was being examined) were compared, and the western ones were seen to fall into larger groups which were therefore pooled;

Table 1. MEAN GENERALIZED DISTANCES FOR GORILLA SKULLS: COMBINED DATA FOR MALES AND FEMALES, CRANIA AND MANDIBLES

	Deme A	Deme B	Deme C	Deme D	Utu	Mwenga-Fizi	Tshiaberimu	Virunga
<i>G.g.gorilla</i> : Deme A								
Deme B	3.42							
Deme C	2.36	1.87						
Deme D	3.75	3.64	2.76					
<i>G.g.manyema</i> : Utu	10.58	7.19	8.98	12.00				
Mwenga-Fizi	13.97	9.63	12.01	13.39	2.61			
Tshiaberimu	18.32	12.80	17.69	19.91	5.26	2.85		
<i>G.g.beringei</i> : Virunga	19.35	14.27	15.63	19.55	8.10	5.78	4.06	

\* For a catalogue of the gorilla material in the British Isles, see Groves and Napier<sup>15</sup>.

the larger groups corresponded exactly to the four-fold division described here, even to the extent of the coast group (A) which includes the inland Mambili skulls. Division was fairly sharp between neighbouring groups in different areas, for example, between Bipindi (on the Cameroun coast) and Ebolowa (a few miles inland, on the plateau); here it seems that gene exchange has not been sufficient to counteract the ecological difference. Likewise the uniformity of the Sangha gorillas (C) was maintained, even though the very considerable isolating barriers of the rivers Sangha and Dja separate the three groups concerned; morphology seems here to be affected more by environment than by isolation. Thus reduced in number, the remaining eight broad divisions show an interesting pattern of diversity. The Nigerian gorillas are fairly distinct from all others in the western area; the coast group is distinct from the plateau group, but the Sangha group is intermediate. For none of the canonical variates (from which the generalized distance table was calculated) do the means of these groups lie more than one standard deviation apart; no sub-specific distinction is involved.

Among eastern gorillas, the Virunga skulls stand out from the other populations more than any of the western groups differ from one another. The other three eastern groups do not differ very much from each other, but show varying degrees of resemblance to the western or the Virunga gorillas. The Utu group of skulls, it will be seen, is almost equidistant from the Virunga group and from the western groups generally; among the latter it bears rather more resemblance to the Plateau group than to the others. By reference to the original canonical variates it is possible to show that there is a significant difference at the 90 per cent level from both Virunga and the western populations, and that the Utu gorilla merits separation at the sub-specific level from both of the others. This is a not unexpected consequence of the discovery, largely pin-pointed by Schaller, that this is an eastern gorilla that is decidedly not a "mountain" gorilla. The Mwenga-Fizi and Tshiaberimu gorillas are intermediate between Utu and Virunga, but nearer to the former, that is, the cline is "stepped": they would therefore be most justifiably placed with the Utu population in the same

sub-species. Renewed examination of the canonical variates showed that it was characters of the jaws and teeth that most weighted the results.

The newly recognized race, being largely a lowland forest form, may be referred to as the eastern lowland gorilla. The two mountain-living populations have been known as *Gorilla graueri* Matschie, 1914, and *Gorilla gorilla rex-pygmaeorum* Schwarz, 1927, names given to the Mwenga-Fizi and Tshiaberimu populations respectively. It would be unfortunate were the race to be known under a name given to an atypical population. Fortunately it is possible to determine that there is a valid, earlier name attached to the Utu population. In 1908, Rothschild<sup>17</sup> referred to a skull in his possession as that of "*Gorilla gorilla manyema* Alix and Bouvier, from the south Congo region". The intention is to indicate a form described by Alix and Bouvier as *G. mayema*; the misspelling would seem to indicate that there was confusion here with Manyema, a province of the Belgian Congo on the upper Congo (Lualaba) region—an area where the eastern lowland gorilla is found. (The actual type locality of Alix and Bouvier's form was Conde, near Landana, on the lower Congo.) If this reading of the evidence is correct, then clearly Rothschild was referring to the eastern lowland gorilla, and *manyema* will be the valid name for the sub-species. Additionally, it must be stated that there is in the British Museum (Natural History) a skull, number 1939.945, from the Rothschild bequest, which bears no information on the label; but on the braincase can be discerned, in faded ink, the inscription "*Gorilla gorilla manyema*. Upper Congo". Rothschild never indicated in any of his papers that he possessed more than one skull of this form, and so B.M. No. 1939.945 is doubtless the holotype of the race. Indeed, metrically, it would be difficult to find a more typical skull of the eastern lowland gorilla.

Several skulls were available of populations whose status is in doubt, and of which large enough samples were impossible to obtain for the primary analysis. From application of the results of the analysis to these skulls, it would seem that the gorillas from the Kayonza forest, Uganda, may be *G.g.manyema*, while those from Mount Kahuzi, west of Lake Kivu, are very possibly *G.g.beringei*.

Fig. 1. Map to show distribution of gorilla demes and sub-species. (A) *G.g.gorilla*, coast; (B) *G.g.gorilla*, plateau; (C) *G.g.gorilla*, Sangha; (D) *G.g.gorilla*, Nigeria; (E) *G.g.manyema*, Utu; (F) *G.g.manyema*, Mwenga-Fizi; (G) *G.g.manyema*, Tshiaberimu; (H) *G.g.beringei*, Virunga; (J) Kayonza forest; (K) Mt. Kahuzi; (L) Bongo, Uele valley.

The skulls from Bondo, in the Uele valley (a locality intervening between the eastern and western zones<sup>10</sup>), are decidedly *G.g.gorilla*.

In conclusion, the gorilla forms but a single species, whose characters overlap in the different races. There are three valid sub-species, at least two of which have ecologically differing demes (for an earlier use of demes as quasi-taxonomic units, see ref. 18). They are as follows: *Gorilla gorilla gorilla* Savage and Wyman, 1847; western gorilla. *Gorilla gorilla manyema* Rothschild, 1908; eastern lowland gorilla. *Gorilla gorilla beringei* Matschie, 1903; eastern mountain gorilla. It may be noted that Vogel<sup>12</sup> similarly concluded that two full sub-species exist in the eastern region, but on quite different grounds. An examination of post-cranial features also supports this conclusion.

I thank all who made gorilla material available for this investigation, especially Dr. G. B. Corbet, Miss J. H. King, Mr. J. E. Hill, Mr. R. W. Hayman and Miss J. Ingles; Mr. L. Barton and Mrs. H. B. Powell-Cotton; Dr. F. Poll and Monsieur D. F. E. Thys; Professor K. Zimmermann and Dr. G. H. W. Stein; and Mr. W. Scheele and Mr. R. Hansen. Mr. Michal Clarke of the Maudsley Biometrics Unit and the staff of the University

of London Institute of Computer Science gave computational help and Professor M. R. Healy gave statistical advice. I also thank Dr. J. R. Napier, of the Royal Free Hospital, and his assistant, Miss B. I. Dickson.

## Polarized Light and Underwater Vision

by

J. N. LYTGOE

Medical Research Council,  
Vision Research Unit,  
Institute of Ophthalmology,  
London, W.C.1

C. C. HEMMINGS

Department of Agriculture  
and Fisheries for Scotland,  
Aberdeen

Many invertebrates are able to distinguish the plane of polarized light. Does this enable them to see further underwater? Experiments carried out in Malta show that the ability to analyse the plane of polarized light may indeed be an advantage in clear water.

It now seems to be established that many invertebrates<sup>1</sup>, including *Octopus*, are able to distinguish the plane of polarized light<sup>2</sup> while the adipose eyelids of some fishes are birefringent and may act as polarizing filters<sup>3</sup>. Underwater spacelight is polarized as a result of the scattering of sunlight, and it has been suggested that the plane of polarized light might be used as a navigational aid by some animals underwater<sup>4</sup>. In an attempt to find out whether the ability to distinguish the plane of polarized light could have any effect on the distance that objects can be seen underwater, a polarizing screen (a lens from a pair of polarizing sunglasses) was taken underwater while aqualung diving off Malta. When the screen was rotated in front of the eye it was evident that the plane of maximum polarization (e-vector) lay at right angles to the Sun's rays in the expected way<sup>4</sup>, but further, when the screen was oriented to exclude the maximum spacelight, it was observed that the apparent brightness of the small fishes present (chiefly Sparidae and an *Atherina*) was reduced less than the background spacelight, and hence fishes stood out in greater contrast against their background. Furthermore, there was a strong subjective impression that the more distant individuals, although invisible to the naked eye, became visible using the polarizing screen.

Two experiments (one photographic, one visual) were carried out to test these observations. In the photographic experiment four rectangles, 15 cm × 20 cm, were painted black, white and mixtures of the two to produce two shades of grey, using I.C.I. 'Kemobel'

chemical resistant paint. When a polarized light source is shone on the painted targets underwater the reflected light is very largely depolarized, and in the experiments to be described it is reasonable to assume that the image-forming light from the targets is essentially unpolarized. The four rectangles were bolted to a 'Perspex' sheet held in a rigid frame resting on a rocky bottom as shown in Fig. 1. A Rolleimarin camera with its standard 'Rolleipol' polarizing filter was used. The filter was mounted on the camera in such a way that the surface reflexion from a bowl of water in air was reduced to a minimum. The target display was photographed against an unobstructed water background at ranges which varied from 3 m to 8 m and at several depths between 3 m and 40 m. First a photograph was taken with the camera held upright. The camera was then rotated through 90° and another photograph taken. The photographs were taken during August 1-3, 1966, between the hours 1300 to 1500 local time, with a cloudless sky. Taking into account the orientation of the camera and target with respect to the Sun, the e-vector should be tilted at about 15° to the horizontal<sup>4</sup>. One such photographic pair is shown in Fig. 1. It appears that the background has undergone a greater brightness change than the targets, and indeed one target which was brighter than its background with the camera held upright was darker when the camera was horizontal.

It is likely that such gross differences should be reflected in the distance at which the targets became invisible when seen underwater. This was tested by fixing two polar-

izing screens to the outer surface of a diver's faceplate and orientating them to exclude the maximum underwater spacelight. Four target displays were used, each similar to those in Fig. 1 except that sixteen targets of different brightness were distributed among the four displays. The brightness of each target was measured by making an underwater brightness match against a standard range of grey ceramic tiles. The horizontal range at which each target just became invisible was measured by a technique previously used and proved reliable<sup>5</sup>. Added precautions were taken, however, to hold the target display as steady as possible in the water by means of one front and one rear guy rope extending from each corner and anchored to the bottom. The target display was moored midway between the surface and the bottom, which was a flat meadow of *Zostera* lying at a depth of 7 m. The display was sited so that it was due north of the observer, and because the sightings shown in Fig. 2 were made between 1330 and 1430 on August 25, 1966, the e-vector was very nearly horizontal. The first series was made with the polarizing screens in place; the screens were then removed and the second sighting series made. There were, however, a number of factors which reduced the precision of the measurements. Despite the guy ropes, that target display rocked slightly in the swell. The refraction of sunlight through the surface ripples caused a dappling of light on the target. Bright unfiltered light was able to reach the eye between the edges of the polarizing filters and the opaque rubber mask and this may well have reduced the range at which the targets should be seen when the polarizing filters were used. Finally, the toughened glass of which the divers' face plates are made is partially birefringent and will have reduced the effectiveness of the polarizing filters. Nevertheless, it is quite clear from Fig. 2A that the polarizing filters increased the range at which objects brighter than the water background could be seen although the visible range of darker objects decreased.

Le Grand<sup>6</sup> and Duntley<sup>7</sup> have derived equations which show that, as a horizontally seen object recedes from the eye underwater, the brightness contrast presented by the object against its water background falls exponentially at a rate determined by the attenuation coefficient of light through the water.

The contrast between the object,  $iN$ , at distance  $r$  and the water background,  $bN$ , is defined as follows

$$C_r = \frac{iN_r - bN}{bN}$$

and the contrast is reduced with horizontal distance thus<sup>7</sup>

$$C_r = C_0 e^{-\alpha r}$$

Fig. 1. The target array photographed at a depth of 3 m and at a range of 7 m through a polarizing filter. In A a photograph was taken with the camera held horizontally, and in B after it had been rotated through 90°.

Fig. 2. A, The range at which grey targets just become invisible when viewed horizontally against the background spacelight. Filled circles, polarizing screens in place; open circles, polarizing screens absent. B, Calculated relationship between target brightness and visible range. Solid line, polarizing screens in place; broken line, no polarizing screens.

where  $\alpha$  is the total attenuation coefficient of image-forming light.

When  $C_0$  falls below about  $\pm 0.02$  for a typical observer in good light<sup>8</sup>, the object becomes invisible. In the case of a black object  $iN_0 = 0$  and  $C = -1$ . Hence  $\alpha$  can be calculated if the distance at which the object just becomes invisible is known as it is here. The relative values for  $iN_0$  for the sixteen different targets have been measured and, because the target which becomes invisible at the shortest distance is the one which most closely matches the background spacelight, the relative value of  $bN$  is known both with and without polarizing filters. Fig. 2b shows that expected relationship between  $r$  and  $iN_0$ , both using a polarizing screen when  $bN = 2.5$  and without when  $bN = 4.0$ . In both cases  $\alpha$  is 0.212. There is a reasonable fit between prediction and practice except for the brighter targets, which are not visible at as great a range as might be expected. We have as yet no adequate explanation for this.

There is no doubt that in these relatively clear waters the ability to analyse the plane of polarized light will in some circumstances confer a real visual advantage on an animal. Because the plane of maximum polarization may tilt by more than 45° at low Sun elevation<sup>4</sup>, and because dark objects are hardest to see when the polarizing screen is orientated to render bright objects most visible (and vice versa), it follows that a simple polarizing screen in the eye of fixed orientation will be less versatile than the system found in *Octopus* (common around both experimental sites), where there is the intra-ocular ability to distinguish light polarized in one plane from that polarized in another.

## Unified Model for Interstellar Extinction and Polarization

THE development of improved techniques for measuring interstellar extinction and polarization has led to a revival of interest in the investigation of grain models. The interstellar extinction curve has recently been extended by Stecher<sup>1</sup>, using rocket techniques, as far as  $\sim 1200 \text{ \AA}$  in the far ultra-violet. It has already become clear that the conventional dirty ice grain model must be ruled out for several reasons. This model cannot explain the detailed shapes of the extinction curves for the visible spectral region obtained by Nandy<sup>2</sup>; nor can it reproduce even the qualitative features of the near and middle ultra-violet observations<sup>3,4</sup>.

It has been shown by Stecher and Donn<sup>5</sup> that a size-distribution of graphite particles could reproduce the structure of the extinction curve up to  $\sim 2000 \text{ \AA}$ , but again no agreement is possible for shorter wavelengths. We have now performed theoretical extinction computations for graphite grains covered with dirty ice mantles with a view to matching the entire wavelength range of the observed interstellar extinction up to about  $1200 \text{ \AA}$ . Experimentally determined values<sup>6</sup> for the refractive index of graphite were adopted for the cores, and the mantle refractive index was taken to be  $m = 1.33 - 0.5i$ . For a graphite core of radius  $r_c = 0.054 \mu$  with a dirty ice mantle of outer radius  $r_m = 0.16 \mu$  good agreement with the entire wavelength range of the extinction law is obtained (Fig. 1). In Fig. 2 the detailed agreement in the visible with Nandy's Cygnus curve is shown. Normalized extinction values are set out in Table 1.

Table 1. THEORETICAL NORMALIZED EXTINCTION VALUES FOR A GRAPHITE CORE OF RADIUS  $0.054 \mu$  SURROUNDED BY A DIRTY ICE MANTLE OF OUTER RADIUS  $0.16 \mu$

$\lambda^{-1} (\mu^{-1})$	$\Delta m$	$\lambda^{-1}$	$\Delta m$
0.00	-0.74	2.22	1.00
0.47	-0.65	2.49	1.15
0.86	-0.35	2.78	1.33
1.19	-0.03	3.01	1.47
1.22	0.00	3.85	1.91
1.56	0.35	4.54	2.22
1.80	0.61	5.00	2.52
		6.67	3.02

The present fit for grains of a single size must be interpreted to imply that there exists on the average, in the line of sight of a star, a bivariate size distribution in  $(r_c, r_m)$  such that the maximum contribution to the integrated extinction arises from particles with  $r_c \approx 0.054 \mu$ ,  $r_m \approx 0.16 \mu$ .

Fig. 1. Theoretical extinction curve for a graphite core of radius  $0.054 \mu$  with a dirty ice mantle of outer radius  $0.16 \mu$ . Normalization is to  $\Delta m = 0$  at  $\lambda^{-1} = 1.22 \mu^{-1}$ ,  $\Delta m = 1$  at  $\lambda^{-1} = 2.22 \mu^{-1}$ . Filled circles represent the observations of Nandy<sup>2</sup> for the Cygnus region; filled circles with error bars represent the ultra-violet observations of Stecher<sup>1</sup>.

Fig. 2. Comparison of the theoretical extinction curve for a graphite core of radius  $0.054 \mu$  with a dirty ice mantle of outer radius  $0.16 \mu$  with the extinction law in the visible for the Cygnus region. Points represent Nandy's observations<sup>2</sup>; open circles represent infra-red observations of Johnson and Borgman<sup>13</sup>.

Fig. 3. Normalized polarization  $\Delta m_p$ . Normalization to  $\Delta m_p = 1$  at  $5000 \text{ \AA}$ . Curve 1 is theoretical polarization for a graphite core of radius  $0.054 \mu$  with an ice mantle of outer radius  $0.16 \mu$ . Curve 2 is theoretical polarization for a graphite flake of radius  $0.11 \mu$ . Points are observations of Coyne and Gehrels<sup>8</sup>.

In a recent article, Wickramasinghe *et al.*<sup>7</sup> have discussed the problem of matching the observed wavelength dependence of interstellar polarization with graphite grains or graphite core-ice mantle grains. It was shown that very small graphite grains of radii  $\sim 0.05 \mu$  do not give rise to the correct wavelength dependence of polarization, but that larger graphite grains or graphite core-ice mantle grains are more satisfactory in this respect. Following the procedure described in this earlier article<sup>7</sup> we have computed a normalized polarization for the present model which gives the best fit with the extinction observations. The normalized polarization curve for this case is plotted as curve 1 in Fig. 3. The points are the polarization observations of Coyne and Gehrels<sup>8</sup>. Taking account of the wide scatter of the observational points, the general fit cannot be regarded as too unsatisfactory. The lack of a closer agreement in the ultra-violet is unlikely to prove a crucial issue, however. Curve 1 is strictly appropriate for the single grain size ( $r_c = 0.054 \mu$ ,  $r_m = 0.16 \mu$ ) which fits the detailed structure of the observed extinction curve. In an actual size-distribution that would be present, it does not follow that the same grain size would produce the maximum contribution to the polarization as well. The polarization will be produced only by those grains which are effectively aligned in the magnetic field. It has been shown by Wickramasinghe<sup>9</sup> that the magnetic field required to align effectively a core-mantle grain with the dimensions in question ( $r_c = 0.054 \mu$ ,  $r_m = 0.16 \mu$ ) is about  $10^{-8} \text{ G}$ . If

the average Galactic magnetic field is about  $10^{-6}$  G, as is currently believed, the situation is that the grain with  $r_c = 0.054\mu$ ,  $r_m = 0.16\mu$  will not be effectively aligned. For a fixed value of the outer mantle radius  $r_m$ , grains with relatively larger graphite cores will be aligned preferentially from any size-distribution<sup>9</sup>. The polarization curve for such particles is, in general, flatter over the entire spectral region of interest, in a way similar to that for large graphite flakes<sup>7</sup>. The normalized polarization curve for a graphite flake of radius  $0.11\mu$ , which would be effectively aligned in a magnetic field of  $\sim 10^{-6}$  G, is given as curve 2 in Fig. 3. The general trend of this curve would be expected to be valid also for a large graphite core covered with very little ice. The agreement between curve 2 and the "mean" observations is seen to be very good.

A further requirement usually demanded of a grain model is that it has a high visual albedo. Although a precise formulation of this condition is difficult, Wolstencroft and Rose<sup>10</sup> reviewing the observational data on the diffuse galactic light have suggested the condition, at the photographic wavelength,

$$\gamma > 0.49 \pm 0.11.$$

For the present grain model with  $r_c = 0.054\mu$ ,  $r_m = 0.16\mu$  the albedo at several representative wavelengths is given in Table 2.

Table 2. ALBEDO OF GRAIN AT REPRESENTATIVE WAVELENGTHS					
$\lambda(\mu)$	0.3322	0.4016	0.5620	0.6410	0.8403
Albedo $\gamma$	0.64	0.60	0.55	0.53	0.45

The computed albedo is seen to satisfy the required condition amply.

## PLANETARY SCIENCE

### Land's End Granites and Their Relation to the Experimental Granite System

RECENT work on the experimental granite system<sup>1,2</sup> has established a series of quaternary minima shifting in the direction of the  $\text{NaAlSi}_3\text{O}_8$  apex with increasing water vapour pressure, and becoming eutectic points at pressures in excess of 3.6 kbars. The "ternary" diagram (Fig. 1) shows the composition of six points at which components simultaneously melt under given isobaric conditions, each of these points representing minimum temperatures on the experimental granite solidus<sup>1,2</sup>. It is thought that crystallization in the natural granite system, in the presence of volatiles the vapour pressure of which

was decreasing, produced trends very similar to those of the experimental system. Field evidence and chemical data<sup>3</sup> support this view, and the widespread occurrence of tourmaline, fluorite, and hydrothermally altered granites in Cornubia<sup>3,4</sup> suggest that boron and fluorine, together with water vapour, fulfilled the role of volatiles. Because of the higher fluxing action of boron and fluorine compared with water, the shift of the quartz-feldspar boundary towards the albite-orthoclase sideline would be accentuated.

These volatiles may have existed as fluoroborates ( $M^+[\text{BF}_4]^-$ ) or trifluoroboroxole ( $\text{BOF}$ )<sub>3</sub>. The existence of fluoroborates in acid igneous magmas could be brought about by the tendency for the boron atom in boron trifluoride to complete its octet by co-ordination with molecules which have lone electrons available for valency purposes. Union with ionized fluorides of alkali metals would therefore give fluoroborates, while reaction with silica would give trifluoroboroxole and silicon tetrafluoride and thus provide a convenient mechanism for "desilicating" complex silicate minerals.

The bulk of the Land's End granite is a coarsely porphyritic rock which discordantly cuts the Mylor Beds and associated basic intrusives producing a metamorphic-metasomatic aureole. Where the coarse porphyritic granite abuts against the hornfels, thermal equilibrium was rapidly attained with the consequent absence of a chilled margin; although where equilibrium was slowly reached sodium-rich felsitic selvages developed<sup>5</sup>. Along parts of the northern contact at Land's End, medium to coarse-grained non-porphyritic granites are emplaced which post-date the main porphyritic types. (The field of marginal granites, Fig. 1, contains analyses of both the sodium-rich chilled phases and the non-porphyritic marginal types.)

Forty-two normative values of granites and aplites from Land's End are plotted in Fig. 1 in relation to the experimental granite system, and show a well defined "aplite field" extending from the silica/feldspar boundary (0.5 kbar) towards the albite corner parallel to the quaternary isobaric points; the more potassic "marginal granite field" is also parallel to this trend and merges into the "main granite field" which extends from the experimental 0.5 kbar isobaric minimum towards the orthoclase apex, thus demonstrating progressive enrichment in potassium.

The "aplite field" which has been shown to represent a "natural ternary minimum" in other south-western granites<sup>6</sup> is probably produced by the many additional

Fig. 1. Triangular variation diagram showing the relationship to the experimental granite system of normative values (catamolecular norms) of forty-two granite and aplite analyses from the Land's End granite, Cornwall. (Partly after Tuttle and Bowen<sup>1</sup> and Luth *et al.*<sup>2</sup>). O, Isobaric eutectic; ●, isobaric minimum; •, granite and aplite norms.

constituents in the natural system modifying, as it were, the less complex experimental system, and as this "natural ternary minimum" will vary areally depending on the fluxes present at any given point, the term "natural ternary minimum field" is considered more appropriate<sup>3</sup>. This field defines the composition of initial melts generated selectively during palingenesis<sup>1,6,7</sup>.

Available data from the Land's End granites (Fig. 1) illustrate the existence of two fields of relatively sodium-rich terms, one including the early granites (marginal granite field) and one including aplites and leucogranites (aplite field), thus supporting the findings of Brammall and Harwood<sup>8</sup> and Exley and Stone<sup>9</sup>. The data delineate a large "main granite field", and furthermore, demonstrate several evolutionary trends. The sodium-rich chilled marginal granites<sup>6</sup> could also represent a natural ternary minimum field and reflect the trend in composition of the invading magma, but since these and the main porphyritic granites have been subjected to potassium metasomatism<sup>3,9</sup> it seems more probable that the "marginal granite field" initially lay closer to the experimental trend, and was subsequently diverted towards the orthoclase apex on metasomatism. Loss of potassium from the centre of the granite would have left it relatively enriched in sodium, thus providing the basis for further differentiation. This, together with filter pressing, produced aplites and leucogranites which ascended through fractures in the main granite which was by now essentially solid. In several marginally "weak" areas along the north-west coastline at Land's End, the inner sodium-rich granite broke through the coarse porphyritic envelope in a similar manner to the St. Austell mass<sup>10</sup>.

It is suggested that some deep seated granite, granodiorite or granite gneiss, underwent differential anatexis<sup>7</sup>, to produce a "milieu mobilisé" the composition of which would lie within the "natural ternary minimum field" and that this quartz-feldspathic liquid ascended through the overlying sediments in much the same manner as other south-western granites<sup>6</sup> (that is, by forceful injection with overhead stoping, and assimilation).

Evidence therefore suggests that the Land's End granites progressed from a sodium-rich magma to a potassium-rich granite by endometasomatism, coevally evolving a sodium-rich core and aplitic "fluids" by differentiation. This produced a series of granites which represent most petrogenetic trends encountered in the south-western pluton, and which are consistent with its regional development.

### Igneous Intrusions and Associated Rocks of the Mangerite-Charnockite Suite

THE demonstration that the pattern of rare earth abundance in a quartz-monzonite from Grenville Township, Quebec, is typical of the pattern shown by most sedimentary rocks<sup>1</sup> is of considerable interest in view of the controversy concerning the consanguinity of anorthosites

with mangerites and kindred rocks of the charnockite suite.

This rare earth pattern is consistent with a metamorphic or ultrametamorphic origin for the charnockitic rocks, and supports the proposals of Hargraves<sup>2</sup> and Berrangé<sup>3</sup>, who have contended that charnockites bordering major Canadian anorthosites are derived from the country rock gneisses.

The Precambrian rocks of the Kap Farvel district in South Greenland (which we are investigating on behalf of the Geological Survey of Greenland<sup>4</sup>) include charnockites with some similarities to those described from Grenville Township. The charnockites partially surround a late plutonic suite of norites, monzonites and rapakivi granites emplaced approximately  $1650 \times 10^6$  yr ago. The igneous rocks clearly intrude the charnockites and may develop an iron-rich border facies against them; however, charnockitic veins also penetrate the igneous suite. A late potash metasomatism, with the potash apparently derived from the country rock, partially obliterates primary features in the border facies.

The charnockites near to the contact with intrusive igneous rocks have extremely complex and apparently chaotic structures but microscopically show equilibrium textures indicative of annealing recrystallization in a static environment. They contain orthopyroxene with abundant clinopyroxene lamellae and feldspars with carlsbad/albite twinning thought by Philpotts *et al.*<sup>5</sup> to be typical of that found in igneous rocks. Away from the contact the charnockites grade structurally, texturally and mineralogically into the surrounding semipelitic and granitic gneisses, which have a relatively simple overall structure and amphibolite facies mineralogy. The field relationships strongly suggest that the charnockites were formed by granulite facies metamorphism and ultrametamorphism of the country rock gneisses. This suggestion is supported by the behaviour of basic intercalations in the gneisses which, as the igneous contact is approached, retain their original directional fabrics but are disrupted by the enclosing charnockitic acid gneiss. Close to the contact of the intrusive igneous rocks the basic fragments are mantled by fine grained pyroxene-rich rock with an equilibrium texture which encloses centres retaining amphibolite facies mineral assemblages and directional fabrics.

Although the charnockitic rocks of the Kap Farvel area are in part igneous, in so far as some appear to have crystallized from locally derived anatectic melts, we believe that—in common with those described by Hargraves and Berrangé—they represent contact metamorphic products better suited to classification and description in terms of mineral facies, rather than in terms of igneous nomenclature which places emphasis on compositional differences. According to this view these charnockites can be regarded neither as having been generated independently of their associated igneous suites<sup>1,5</sup>, nor as being comagmatic with them<sup>6,7</sup>.

## PHYSICS

A Possible Restriction on CP-Noninvariance in  $K^0$ -Decay

THE generally accepted interpretation—which is the only remaining explanation within the framework of quantum mechanics—of the observed  $K_S^0 \rightarrow 2\pi$  decays<sup>1,2</sup> is that this is a manifestation of some CP-noninvariant interaction. Despite a large variety of suggestions as to the nature of the CP-noninvariant interaction, there has so far been no clear indication of CP-noninvariance in any other process and we still remain ignorant of the origin or nature of the interaction responsible for  $K_S^0 \rightarrow 2\pi$  decays. A phenomenological analysis of  $K^0 \rightarrow 2\pi$  decays has been given by Wu and Yang<sup>3</sup>, but experiments carried out so far do not permit a unique determination of the relevant parameters. In the absence of a basic theory, it may be of interest to consider a simplifying assumption, which does not conflict with any known result, which fixes the parameters for  $K_S^0 \rightarrow 2\pi$  decay.

The condition which we wish to discuss is<sup>4</sup>

$$\langle K_1^0 | K_2^0 \rangle = 0 \quad (1)$$

where  $K_1^0$  and  $K_2^0$  are the linear superpositions of  $K^0$  and  $\bar{K}^0$  states which are characterized by a purely exponential time-dependence in the Weisskopf-Wigner approximation. Assuming TCP-invariance, they are given by<sup>5</sup>

$$\begin{aligned} K_1^0 &= (1 + |r|^2)^{-1/2} (K^0 + r\bar{K}^0) \\ K_2^0 &= (1 + |r|^2)^{-1/2} (K^0 - r\bar{K}^0) \end{aligned} \quad (2)$$

where  $r$  is in general a complex constant determined by the dynamics of the  $K^0 - \bar{K}^0$  complex. From relations (2), we see that the condition (1) is equivalent to

$$|r|^2 = 1 \quad (3)$$

From the disparity of  $K_1^0$  and  $K_2^0$  lifetimes, Lee, Oehme and Yang<sup>5</sup> could conclude that  $|r|$  could not differ appreciably from unity. Taking  $|m_2 - m_1| = 0.5 \tau_1^{-1}$ , the restriction that an arbitrarily chosen neutral kaon beam can only decay with time yields the inequalities  $0.95 < |r| < 1.05$ . As is evident from (2), the phase of  $r$  depends on the choice of relative phase of  $K^0$  and  $\bar{K}^0$  states. We adopt the choice of Wu and Yang<sup>3</sup> which makes the amplitudes for  $K^0$  and  $\bar{K}^0$  to decay to the  $I = 0$   $\pi\pi$  scattering eigenstate purely real. A limit on both the magnitude and phase of  $r$  can be obtained from a knowledge of the relative  $2\pi$  decay rates of  $K_1^0$  and  $K_2^0$ . Using the formulae and notation of Wu and Yang, it can be shown quite generally that<sup>6</sup>

$$|(1-r)/(1+r)| \leq 2^{-1/2} \rho^{1/2} (2^{1/2} \rho^{1/2} - 1)^{-1} [2|\eta_{00}| + 2^{1/2} \rho^{-1/2} |\eta_{00}|] \quad (4)$$

where  $\rho$  is the branching ratio  $\rho = \Gamma(K_1^0 \rightarrow \pi^+\pi^-)/\Gamma(K_1^0 \rightarrow \pi^0\pi^0)$ . Even the rough limits which could be imposed on  $|\eta_{00}|$  from knowledge of the  $K_2^0$  lifetime and the partial rates for other decay modes beside  $\pi^0\pi^0$  sufficed to determine that  $r$  is close to unity both in modulus—consistent with condition (3)—and phase (with the Wu-Yang phase convention). Recent measurements<sup>7</sup> of the  $K_S^0 \rightarrow \pi^0\pi^0$  rate, which yield  $|\eta_{00}|$ , reinforce the conclusion<sup>7</sup>. The condition (3) then requires that the small parameter  $\varepsilon = 1 - r$  be purely imaginary,

$$Re \varepsilon = 0 \quad (5)$$

If we assume, in accordance with the  $\Delta I = \frac{1}{2}$  rule, that the  $I = 2$  amplitudes are small compared with those for  $I = 0$ , we have the approximate relations<sup>3</sup>

$$\eta_{+-} = \frac{1}{2}[\varepsilon + \varepsilon'] \quad (6a)$$

$$\eta_{00} = \frac{1}{2}[\varepsilon - 2\varepsilon'] \quad (6b)$$

where  $\varepsilon'$  is a parameter describing the CP-violation in the  $I = 2$  amplitude relative to the  $I = 0$  amplitude. From relations (6a) and (6b), we see that relation (5) requires

$$Re \eta_{00} = -2 Re \eta_{+-} = -2 |\eta_{+-}| \cos \varphi_{+-} \quad (7)$$

where  $\varphi_{+-}$  is the phase of  $\eta_{+-}$ . Equation (7) cannot be satisfied unless

$$|\eta_{00}| \geq 2 |Re \eta_{+-}| = 2 |\eta_{+-}| |\cos \varphi_{+-}| \quad (8)$$

According to Rubbia and Steinberger<sup>8</sup>, the best estimate for  $\varphi_{+-}$  is  $\varphi_{+-} = 0.60 \pm 0.23$  radians. Equation (8) then requires

$$|\eta_{00}| \geq (3.2 \pm 0.6) \cdot 10^{-3} \quad (9)$$

using the value  $|\eta_{+-}| = (1.94 \pm 0.09) \cdot 10^{-3}$  quoted by Cronin *et al.*<sup>2</sup>. The condition (9) requires the presence of appreciable  $I = 2$  amplitudes in  $K_S^0 \rightarrow 2\pi$  decay, because pure  $I = 0$  would give  $|\eta_{00}| = |\eta_{+-}|$ . The likelihood that relation (3) could only be satisfied by an appreciable departure from the  $\Delta I = \frac{1}{2}$  rule in  $K_S^0 \rightarrow 2\pi$  decay was previously noted by Bowen<sup>4</sup>.

According to equation (7), for a given  $\eta_{+-}$ , the magnitude of  $\eta_{00}$  fixes its phase (within a two-fold ambiguity),

$$\begin{aligned} \cos \varphi_{00} &= -2 (Re \eta_{+-})/|\eta_{00}| \\ \varphi_{00} &= \pi \pm \cos^{-1} [2 (Re \eta_{+-})/|\eta_{00}|] \end{aligned} \quad (10)$$

A measurement of the phase of  $\eta_{00}$  is therefore of great interest as a test of the hypothesis (1). Taking the value of  $|\eta_{00}|$  from Cronin *et al.*,  $|\eta_{00}| = (4.9 \pm 0.5) \cdot 10^{-3}$ , we obtain the estimates,

$$\begin{aligned} \cos \varphi_{00} &= -(0.65 \pm 0.20) \\ |\pi - \varphi_{00}| &= 0.86 \pm 0.30 \text{ radians} \end{aligned} \quad (11)$$

The condition (1) has several other interesting consequences. The decay curve of any neutral kaon beam becomes simply the sum of two exponentials; furthermore, there is no charge-asymmetry in leptonic decays of  $K_S^0$ , independent of the  $\Delta S = \Delta Q$  rule<sup>5</sup>. If the  $\Delta S = \Delta Q$  rule holds, the time dependent charge-asymmetry in leptonic decays from a beam which is initially pure  $K^0$  is required to be exactly the opposite to that from a  $\bar{K}^0$  beam. Also, the asymptotic decay rate into any particular channel becomes exactly the same whether we start with initial  $K^0$  or  $\bar{K}^0$  beams.

The significance of the restriction (1) is probably much deeper. Because such a condition scarcely occurs by accident, confirmation of hypothesis (1) would strongly suggest the existence of some hitherto unknown symmetry operation, of which  $K_1^0$  and  $K_2^0$  are distinct eigenstates. The possibility that there might be such a guiding principle beneath the apparent confusion created by the discovery of CP-nonconservation makes a test of the explicit prediction (10) extremely desirable.

I thank Prof. R. E. Peierls for a stimulating discussion.

## Characteristics of Fibre Friction

AMONTONS'S classical law of friction, as explained by the cohesion theory, accounts satisfactorily for most cases of metallic friction. For non-metallic materials, however, and in particular the elastic solid field of polymeric mono-filaments and natural fibrous materials, many exceptions

to his law have been reported<sup>1-4</sup>. In these cases it has been observed that over an appreciable load range, the frictional coefficient ( $\mu$ ) does not remain a constant but decreases as the load increases, which suggests that local deformation occurs at the interface between the polymer and friction object. To explain the variability of  $\mu$ , it has been proposed<sup>5</sup> that the true area of contact and the shear strength vary with the load. For this to be true, Howell<sup>6,7</sup> has shown that the frictional force must be related to the load by  $F = KW^n$ , where  $K$  and  $n$  are constants. (The value of  $K$  depends on the properties of the surface materials while  $n$  is independent of these and is dependent only on the mechanism of deformation, that is,  $n$  is an indicator of the visco-elastic properties of the material under test.) For a fibre or a yarn travelling at a constant speed over a cylindrical object, the change in tension developed in the fibre or yarn is therefore found from the following equation

$$T_2^{(1-n)} = T_1^{(1-n)} + (1-n)KR^{(1-n)}\theta \quad (1)$$

where  $T_2$  and  $T_1$  are the output and input tensions, respectively,  $\theta$  is the angle of yarn wrap, and  $R$  is the radius of curvature of the test object.

In an attempt to study the frictional properties of wool yarns, an instrument was built at this laboratory which measures  $T_2$  and  $T_1$  continuously, using sensitive differential capacitor transducers accurate to  $\pm 0.1$  g. Kinetic measuring of yarn/metal, yarn/yarn frictional behaviour can be performed on most types and counts of yarn, for a variety of  $\theta$  and  $R$  values, and through a linear yarn speed range of about 0–365 m/min. The instrument and its use have been described earlier<sup>8</sup>.

A 64's quality, '92 Tex' worsted yarn (3.4, 1.8 turns/cm) was chosen as a test yarn, and its frictional characteristics were determined running over a hardened steel cylinder, 1.1 cm in diameter, at a constant linear speed of 150 m/min. Values of  $T_2$  and  $T_1$  were collected at approximate increments of  $T_1 = 3$  g, up to a maximum value of  $T_1 \sim 60$  g, and through a range of values of  $\theta$  from 0.59 to 2.97 radians. The best fit values of  $n$  and  $K$  in equation (1) were calculated for the eight values of  $\theta$  chosen (Fig. 1) using a computerized iteration technique first suggested by Rubenstein<sup>9</sup>.

Obviously in Fig. 1 there exists a definite non-linear relationship between  $n$ ,  $K$  and  $\theta$  that is not suggested by equation (1), and on the basis of the existing theory it is difficult to explain these results. It is true that over a very extensive load range  $n$  may vary somewhat<sup>10</sup> and that  $n$  and  $K$  may not be constant with changes in surface roughness and  $R$  (ref. 11), but the variability of  $n$  and  $K$  with  $\theta$  has not previously been reported. In fact, on plotting  $n$  against  $K$  it is found that  $n$  is related to  $K$  in the following curious manner

$$n = \frac{5.46 - K}{5.90} \quad (2)$$

this linear interrelationship being highly significant with a correlation coefficient of  $-0.968$ . Howell's original formula must therefore be correspondingly modified, and it may now be suggested that the frictional force is related to the normal load by the equation

$$F = pW^n - qnW^n \quad (3)$$

where, for a wool yarn, the constants  $p$  and  $q$  are equal to 5.46 and 5.90, respectively.

To explain the relationship in equation (2), E. Menefee has suggested (personal communication) that this may involve an internal fibre friction effect because the tendency of fibres to move laterally past each other will be strongly dependent on the angle involved. In other words,  $K$ , which is supposed to depend on the surface properties, may represent an overall surface effect which includes the interior interactions of the fibres; similarly  $n$ , related to the deformability of the yarn, will probably also be dependent on the ability of the yarn interior to rearrange and thereby also depend on the internal fibre surface

Fig. 1.  $K$ ,  $n$  versus  $\theta$  for '92 Tex' worsted yarn.

properties. Another possible explanation may be that we are observing the effects of boundary conditions of hydrodynamic lubrication, resulting from small amounts of residual natural wool oils and waxes, and not true fibre/metal friction at all. Even though the yarns tested were scoured in preparation and left unwaxed, very thin liquid films, possibly of only molecular dimensions, may still exist to influence the frictional behaviour of the yarn<sup>12</sup>. Evidence to support this possibility has recently come from similar observations made in this laboratory on a multi-filament nylon yarn which carried a known amount of surface lubrication. One other interesting observation in Fig. 1 is the maximum value of  $n$  ( $=0.85$ ) at  $\theta \sim 1.8$  radians. This value corresponds closely with the predicted value of  $n=8/9$  from the hemispherical asperity model suggested by Howell, Mieszkis and Tabor<sup>13</sup>. This result has been shown to be in very close agreement with the findings of other workers<sup>2</sup>.

It thus seems reasonable to suggest that Howell's theory is not valid over a wide range of values of  $\theta$  except at or near  $\theta=1.8$  radians, and that other theories are more likely to predict the observed frictional behaviour of fibres and yarns. In this respect, Whitney<sup>14</sup> thinks that for nylon and polypropylene monofilaments, Gralén's<sup>15</sup> equation that  $F = aW + bW^c$  (where  $a$ ,  $b$  and  $c$  are constants) more adequately agrees with experimental data. Work is continuing here to investigate the application of equation (3) and other theories to the phenomenon of wool fibre friction.

### Increase in d.c. Dark Conductivity of Anthracene in a Magnetic Field

Frankevich and Balabanov<sup>1</sup> have reported magnetic enhancement of the photoconductivity of single crystals of anthracene. Similar effects in the dark conductivity have been observed in this laboratory.

Measurements were made of the d.c. dark conductivity at  $10^5$  V/m in an argon atmosphere, with and without a guard ring, over a period of 12 days. Fig. 1 shows the results for a crystal 1 mm thick which had been degassed in the dark for 3 days before the measurements were undertaken. Evaporated gold electrodes were used because deleterious effects had been observed with metallic pastes. It was found that the methyl-iso-butyl ketone used in "dag" silver preparation slightly reduced the resistivity of the single crystals of anthracene: on  $5\mu$  films of anthracene the resistivity was reduced by three orders of magnitude and the activation energy changed from 0.9 eV to 0.3 eV. This could have arisen from the formation of a charge-transfer complex by the ketone with anthracene or with impurities such as anthraquinone and anthrone.

Fig. 1. Variation of the resistivity of single crystals of anthracene parallel to the "ab" plane with time at 296° K.  $\Delta$ , With guard ring;  $\bullet$ , without guard ring.

We investigated the effect of applying a magnetic field perpendicular to the current through the crystal. Care was taken in all measurements to ensure that stability of temperature and space charge had been secured: this often took up to 4 h. Fig. 2 shows the increase in dark current with magnetic field when the guard ring was used. Fig. 3 illustrates the measurements obtained without the guard ring: they suggest that the results of Fig. 2 were due to a bulk rather than a surface effect. The results were independent of current and field polarity.

The energy gaps for zero and 0.67 Tesla magnetic fields were determined between 255° K and 320° K as 0.84 eV for both conditions within the experimental error of  $\pm 0.02$  eV.

The results shown in Fig. 2 for the magneto conductivity were much greater than and of opposite sign to that allowed by conventional semiconductor theory. Measurements made on single crystals of anthracene in the dark of the Hall current (to be published) suggested a Hall mobility of the order of  $1 \times 10^{-3}$  m<sup>2</sup>/V sec, which can be compared with a similar photoconductive Hall mobility observed by Delacote and Schott<sup>2</sup>. Following Smith<sup>3</sup>, in a field of 0.7 Tesla

$$\Delta\sigma/\sigma_0 \approx -5 \times 10^{-9}$$

Fig. 2. Fractional increase of dark current against magnetic field, with a guard ring. Broken rule, photoconductivity result of Frankevich and Balabanov<sup>1</sup>.

Fig. 3. Fractional increase of dark current against apparent crystal resistivity for a magnetic field of 0.51 Tesla and no guard ring.

Friedman<sup>4</sup> has shown that for narrow band semiconductors the effect would be smaller than this by a factor of  $10^4$  and the Hall effect would be anomalous. Frankevich and Balabanov explained their results for photoconductivity in terms of increased exciton lifetime.

A change in activation energy of less than  $10^{-2}$  eV would account for the magnetoconductivity increase at 300° K. This could result from small shifts and splittings of impurity and molecular energy levels within the Davydov exciton model<sup>5</sup>. Furthermore, the internal space charge reduced the initial crystal current by at least three orders of magnitude and a small decrease in this space charge by diffusion of "trapped" carriers to surface recombination centres could explain the observed magnetoconductivity effect.

## CHEMISTRY

## Valency State of Chromium in Seawater

THE valency state in which chromium occurs in seawater not only provides important information concerning the geochemical behaviour of this element in marine environment but has also in recent years become significant in connexion with the problem of disposal of radioactive waste. For example, Osterberg *et al.*<sup>1</sup> investigated the variation of the spread of the Columbia River water along the Oregon coast of the Pacific by using chromium-51 which was originally released from the Hanford reactor as a radioactive tracer. In this case, it was reported by Cutshall *et al.*<sup>2</sup> that the major part of chromium-51 stayed in the original hexavalent state in seawater even at several hundred kilometres from the river mouth. In order to understand the cycle of radioactive chromium in the seawater, therefore, it seems indispensable to know the valency state in which chromium in seawater is stable. Unfortunately, the present day knowledge of this is very limited. In his recent compilation Riley<sup>3</sup> gave six references for the chromium content of seawater but these data are not sufficient to indicate general trends in the behaviour of chromium in seawater. In these investigations, except for the two investigations by emission spectrography, chromium was separated with hydroxides of aluminium, iron or chromium itself. These separations are only effective when chromium in seawater is present in a trivalent form.

Goldschmidt<sup>4</sup> suggested that chromium was present in seawater in the hexavalent state (chromate), and this was accepted by Krauskopf<sup>5</sup>. Arrhenius and Bonatti<sup>6</sup> supported the idea of a hexavalent state and pointed out the possibility of coprecipitation of chromate with strontium or barium sulphate *in situ*. Fukai and Huynh-Ngoc<sup>7</sup> showed by thermodynamical computations that the stable species of chromium in seawater should be hexavalent. Sillén<sup>8</sup> suggested that uncharged soluble chromic hydroxide might be present.

Because two contradictory ideas exist about the valency state of chromium in seawater, I have devised a differential method for the determination of the trivalent and hexavalent chromium which occurs in seawater. The principle of the method depends on independent measurements of two equivalent samples from the same sample of water, one treated by direct coprecipitation of chromium with iron hydroxide and the other by a similar coprecipitation after reduction with sodium sulphite in acid medium.

The results obtained by the method for samples of water collected from the Ligurian Sea are summarized in Table 1. It can be seen that hexavalent chromium was found in all the water samples. For some of the samples the trivalent chromium estimated was within the range of analytical sensitivity. These results seem to support the thermodynamical estimation of the valency state of chromium given by Fukai and Huynh-Ngoc<sup>7</sup>. The thermodynamically unstable species, trivalent chromium, however, was detected in many cases. This fact suggests that there

is some process which is working against thermodynamic equilibria.

## Some Reactions of Triruthenium Dodecacarbonyl

WE have been investigating some reactions of triruthenium dodecacarbonyl  $\text{Ru}_3(\text{CO})_{12}$ . The structure of this compound is well established as an equilateral triangle of three ruthenium atoms with twelve terminal carbonyl groups<sup>1</sup>. The reactivity of this compound towards halogens, thiols, olefines and related compounds is, however, virtually unexplored. Some similarity in its chemical reactivity to that of tri-iron dodecacarbonyl can be expected, but whereas reactions of the iron cluster normally lead to cleavage of the trimeric unit, the ruthenium analogue appears to give stable trinuclear species. This may be correlated with an increase in the stability of metal-metal bonds on going down the transition metal triad<sup>2</sup>. This communication summarizes some of the reactions carried out on ruthenium carbonyl.

**Reaction with halogens.** Oxidation of triruthenium dodecacarbonyl with halogens ( $\text{X}_2$ ) ( $\text{X} = \text{Cl}, \text{Br}$  or  $\text{I}$ ) has led to the isolation of four classes of ruthenium carbonyl halides, namely: (i) The monomeric  $\text{Ru}(\text{CO})_5\text{X}_2$  (ref. 3). (ii) The dimeric  $\text{Ru}_2(\text{CO})_8\text{X}_4$ ;  $\text{Fe}(\text{CO})_5\text{Br}_2$  (ref. 4) and  $\text{Os}(\text{CO})_5\text{X}_2$  (ref. 5) reported previously may be of a similar type. (iii) The trimeric  $\text{Ru}_3(\text{CO})_{12}\text{X}_6$  which to our knowledge represent the first examples of a new class of trimeric carbonyl halide. This class of compound emphasizes that the metal cluster unit appears to behave in a novel way by donating six electrons to available groups. We have previously observed this behaviour in the compound  $\text{Os}_3(\text{CO})_{12}\text{OsO}_4$  (ref. 6). The fact that no analogues of iron are known may be correlated with the enhanced stability of metal-metal bonded compounds in the higher oxidation states of second and third row transition metals. The molecular weights of these compounds ((i), (ii) and (iii)) are based on the appearance of the parent molecular ions in the mass spectra. (iv) The polymeric carbonyl halides  $(\text{Ru}(\text{CO})_2\text{X})_n$  (ref. 7).

**Reaction with thiols.** Reaction of triruthenium dodecacarbonyl with thiols follows a different course from that

observed with halogens, and in these reactions the compounds  $\text{Ru}_2(\text{CO})_9\text{S}_2\text{R}_2$ ,  $(\text{Ru}(\text{CO})_5\text{S}_2\text{R}_2)_n$  ( $\text{R} = \text{Me}, \text{Et}, n\text{-Bu}, \text{Ph}$ ) and  $\text{Ru}(\text{SR})_3$  ( $\text{R} = \text{Ph}$ ) are the principal products. The structure of  $\text{Ru}_2(\text{CO})_9\text{S}_2\text{R}_2$  is expected to be similar to that of  $\text{Fe}_2(\text{CO})_9\text{S}_2\text{Et}_2$  which is well established<sup>8</sup> as dimeric with sulphur bridges. The polymeric  $(\text{Ru}(\text{CO})_5\text{S}_2\text{R}_2)_n$  compounds are similar to the polymeric halides  $(\text{Ru}(\text{CO})_5\text{X}_2)_n$  which are believed to have a halogen-bridged kinked chain structure with *cis* carbonyl groups<sup>9</sup>.

**Reaction with phosphines.** Reaction of triruthenium dodecacarbonyl with  $\text{PPh}_3$  gives  $(\text{Ph}_3\text{P})_3\text{Ru}_3(\text{CO})_9$ . A complex of this analytical description has already been reported<sup>10</sup>. The infra-red spectrum in the carbonyl stretching region (Table 1) of the complex produced in this work is, however, substantially different from that reported earlier. We believe that this discrepancy may be accounted for by the formation of isomers.

**Reaction with dienes.** Triruthenium dodecacarbonyl reacts with 2,5-dihydroanisole in benzene at reflux temperature to give dihydroanisole ruthenium tricarbonyl. Unlike the reaction with iron carbonyls, which produces two isomers (I) and (II) in yields<sup>11</sup> of about 30 per cent and 70 per cent, respectively, isomer (I) is the principal product. Previous work has shown that the free diene corresponding to isomer (I) is thermodynamically unstable. The production of this isomer as the stable species on co-ordination to the  $\text{Ru}(\text{CO})_3$  group is therefore of particular significance. As with the iron derivative, reaction with trityl tetrafluoroborate leads to hydride abstraction from the organic ligand (see reaction scheme).

A similar reaction with dihydrobenzene yields the dihydrobenzene ruthenium tricarbonyl derivative.

### Chemiluminescence of Humic Acids

THE concept that humic acids (HA) are heteropolycondensates of phenolic substances is now widely accepted<sup>1,2</sup>. All the humic acids have hydroxyl, methoxy, or carbonyl groups connected with the aromatic parts of the nucleus. Our earlier investigations suggested that oxidation of hydroxyl groups attached to the aromatic ring may be accompanied by chemiluminescence<sup>3-5</sup>. It seems probable that chemiluminescence by analogy with fluorescence<sup>6</sup> may be able to provide information about the physical and chemical properties and the mechanism of oxidation of the humic acid. Furthermore, the emission of radiation in the course of the oxidation of humic acids may have physiological effects, especially if ultra-violet radiation is present. We have undertaken an investigation in order to gain more detailed information on this problem.

Table 1. CHARACTERISTICS OF HUMIC ACIDS

Sample No.	Origin	Extraction	Purifying procedure	Elementary analysis (per cent)			
				C	H	N	ash
1	Podzol soil	0.5 normal sodium hydroxide after decalcification with 2 per cent hydrochloric acid	Precipitation, centrifugation, dialysis	40.32	4.12	3.43	7.9
2	Black soil			41.59	4.26	2.15	10.1
3a	High peat	0.1 normal sodium hydroxide	Precipitation, centrifugation, dialysis, extraction with ethanol	Ethanol insoluble fraction			
3b				ethanol soluble fraction			
				46.2	3.79	3.94	-
				40.6	5.12	4.02	-

Table 1 contains the characteristics of humic acid samples. The equipment used for the luminescence measurements consists of an externally silvered, hemispherical cuvette mounted on a multiplier phototube, sensitive in the spectral region 390–500 nm<sup>4,7</sup>. Aqueous solutions of sodium humates (1, 2, 3a, Table 1) and a 0.05 per cent ethanolic solution of hymatomelanic acid (3b, Table 1) were oxidized with 0.185 molar hydrogen peroxide in the presence of 0.125 molar sodium carbonate. The luminescence intensity (*I*) was then recorded as a function of time (*t*) under varying concentrations of humic acids, hydrogen peroxide, and hydroxyl ions, at various temperatures and in the presence of the same catalysts and inhibitors (Fig. 1).

Weak visible chemiluminescence was found in the spectral region between 400–600 nm. The curves of light intensity against time gave  $I_{\text{max}}$  and  $E_{h\nu/3} = \int_{t=0}^{t=3} I dt$ , where *t* is the time in min (Table 2). We found that the maximum light intensity and the maximum value of  $E_{h\nu/3}$  are

$$E' = \left( \frac{E - E_k}{E_k} 100 \right)_{h/3 \text{ min}}$$

$I$ ,  $E$ , Maximum intensity and light sum, respectively, in the presence of catalysts or inhibitors;  $I_k$ ,  $E_k$ , the same without catalysts or inhibitors.

Fig. 1. Time course of chemiluminescence during oxidation of different humic acids (0.05 per cent) with 0.180 molar hydrogen peroxide and 0.125 molar sodium carbonate. Temperature, 30° C; supply voltage, 1,040 V. Humic acids or hydrogen peroxide and sodium carbonate were injected at the points indicated by the arrows. The inset in the upper right portion of the figure is a graph of maximum intensity  $I_{\max}$  against concentration for particular reagents.

reached where there is a large excess of hydrogen peroxide and hydroxyl ions:

$$\frac{[\text{H}_2\text{O}_2] \%}{[\text{HA}] \%} = 140, \quad \frac{[\text{NaOH}] \%}{[\text{HA}] \%} = 2.4$$

The temperature coefficient  $k_t = \frac{(I_{\max})_t + 10}{(I_{\max})_t}$  is  $1.89 \pm 0.18$

for the humic acid (row 3a of Table 1) and  $1.58 \pm 0.33$  for hymatomelanin (row 3b) in the range 15–30° C. A plot of  $\ln I_{\max}$  against  $1/T \times 10^3$  gives a straight line both for the HA and HMA. Activation energies calculated from the slope of these lines are  $12.78 \pm 2.11$  and  $8.03 \pm 1.01$  kcal/mole, respectively. The values of activation energies, quenching effects of  $\alpha$ -naphthol, phenol and an activation chemiluminescence by ions of heavy metals ( $M^{+n}$ ) suggest that the light emitting species are generated in radical reactions.

The first step in the consecutive reaction involves the decomposition of hydrogen peroxide

In the next stages, the anions and/or radicals OH, OOH, O<sub>2</sub> react with the humate anion, producing a smaller and simpler molecule in an excited state

The results shown in Table 2, concerning the effects of boracic acid, peroxidase and ascorbic acid, indicate that this step involves an oxidation of phenolic groups and breakdown of the aromatic rings of humic acid molecules.

In order to confirm this suggestion, absorption spectra of the humic acids from 320–600 nm were investigated.

$\Delta \log k$ , which is logarithm of the ratio of absorption coefficient at 400 nm to that at 600 nm, was 0.83 and 0.63 before oxidation for the humic acid and hymatomelanin acid samples shown in Table 1 (3a and b) respectively and 0.87 and 0.59 after oxidation. Decreases of absorption at 400 nm ( $\Delta E_{1\text{cm}}^{400}$ ) after oxidation for 3 min were 12.0 and 6.3 for samples 3a and 3b. This fact shows that the oxidation products of humic acids are less condensed than HA due to the breakdown of aromatic rings.

Further work is in progress to determine the spectrum and quantum yield, and, if possible, to establish the physiological role of the excited states of oxidation products of humic acids and that of emitting radiation.

### Antimalarial Activity of Prodigiosin

SINCE Babès in 1885 claimed the complete inhibition of cholera vibrio by an old culture of *Micrococcus prodigiosus* there have been numerous descriptions<sup>1-3</sup> of antibiotic properties associated with the bacterium *Chromobacterium prodigiosum* (*Serratia marcescens*) and the bipyrrylpyrrolylmethene prodigiosin (I), which occurs in the red bacterial pigment. The purity of the metabolite<sup>4,5</sup> used in the earlier investigations is suspect and the earlier claims like those for the bacterium lack definition of the true causative factor. In this regard the prodigiosin used has been considered too toxic for therapeutic use, although it has evidently been used in the clinical treatment of some cases of disseminated coccidioidomycosis (San Joaquin Valley

fever)<sup>6</sup>. Goble and Boyd<sup>7</sup> examined a number of porphyrins, bilirubinoids, pyrroles and congeners against *Trypanosoma congolense* in mice and found chlorophyllins, containing either magnesium or copper, and haematoporphyrin to be effective in delaying death and curative with prolonged treatment. We have investigated the antimalarial properties of purified prodigiosin (I), the cyclotetradepsipeptide serratamolide (II)<sup>4,8,9</sup>, an ethyl alcoholic extract of *Serratia marcescens* (III) from which I, II and other metabolites can be derived<sup>4</sup>, and two dipyrrolylmethenes (IV a and b) against *Plasmodium berghei* in mice. Prodigiosin showed definite activity (Table 1) against the parasite, which took about twice as long to kill the mice as compared with untreated infections, whereas the other materials exhibited only weak activity at the same or comparable concentrations.

Table 1. ANTIBIOTIC ACTIVITY OF PRODIGIOSIN AGAINST *Plasmodium berghei* IN MICE

Prodigiosin (mg/kg body wt.)	Deaths on indicated day (post infection)				Mean survival time (days)		Toxic deaths
					Treated	Control	
40	1/9	1/10	1/13	1/14	—	—	0
40	1/9	1/10	1/13	1/14	1/17	12.6	6.3
40	2/9	1/10	1/13	1/14	—	11.0	6.2
40	2/9	1/10	1/13	1/14	—	11.0	6.2
40	2/9	1/10	1/13	1/14	—	11.0	6.2
160	1/5	1/13	2/16	—	—	—	1
160	1/5	1/13	2/16	1/17	15.5	6.3	1
160	2/5	1/14	1/15	—	—	6.2	2
160	2/5	1/14	1/15	1/19	16.0	6.2	2

For each test, five 30 day old female mice were infected with a lethal dose of parasites 3 days before subcutaneous administrations of prodigiosin in peanut oil.

At 640 mg/kg all treated mice were dead by the fifth day, with the mean survival time for controls at 6.2–6.3 days.

This investigation was supported in part by grants from the U.S. National Institute of Allergy and Infectious Diseases and the U.S. National Cancer Institute. Antimalarial results were kindly furnished by the Walter Reed Army Institute of Research.

## BIOCHEMISTRY

### Phylogenetic Relationships of Echinoderms : Biochemical Evidence

THE conclusion that present day asteroids and ophiuroids have descended from the crinoids by way of somasteroids<sup>1</sup> has been challenged by G. M. Philip<sup>2</sup>, who argued that palaeontological evidence would not bear out the apparent homologies of structure of living sea-stars and crinoids. Fell, the proponent of the theory, has given a seemingly adequate reply<sup>3</sup>. Both authors, however, appear to be unaware of, or have chosen to ignore, evidence from comparative biochemistry that clearly has a bearing on the problem of the relationships of the echinoderm phyla:

it suggests that crinoids may lie on a different line of descent from any of the other four classes. In fact, in so far as biochemistry constitutes acceptable evidence, it makes Fell's proposal that Somasteroidea, Asteroidea and Ophiuroidea are sub-classes of class Crinoidea<sup>1</sup> appear to be untenable.

In a review published posthumously<sup>4</sup>, Bergmann discussed the comparative biochemistry of the sterols. He pointed out that comprehensive studies of the sterols of echinoderms<sup>5</sup> had confirmed his previous observation that the predominant sterols of ophiuroids and echinoids were the strongly laevorotatory  $\Delta^5$ -sterols. Cholesterol was usually the only component, although it was sometimes accompanied by elionasterol, poriferasterol and stigmasterol. On the other hand, the sterols of asteroids and holothurians were invariably a mixture of weakly dextrorotatory compounds,  $\Delta^7$ -stellasteruol, and its 22,23-dehydro derivative, stellasterol\*. The latter two classes also contain batyl alcohol<sup>6,7</sup>, the 1-O-octadecyl ether of glycerol. Extracted with the lipids, and non-saponifiable, batyl alcohol had once been thought to be a sterol and had been variously named astrol<sup>8</sup> and asteriasterol<sup>9</sup>. It is not generally found in the fats of ophiuroids and echinoids<sup>5</sup>.

The distribution of energy-rich amidine phosphates (phosphagens) should also be considered here. Although Huennekens and Whitely have concluded that the type of N-phosphate compound present in a given phylum does not appear to constitute a valid criterion of phyletic relationship<sup>10</sup>, there is a certain regularity of occurrence among the echinoderms. The exceptions have been found only in sperm tissue and not among adult animals, the distribution for which<sup>11</sup> is shown in Table 1, which also summarizes the distribution of sterols and batyl alcohol.

If we consider, as Florkin does<sup>12</sup>, that compounds with a common chemical lineage are homologous (while compounds exercising the same function in different organisms are analogous), then it is clear from the boxed-in portion of Table 1 that the Asteroidea and Holothuroidea contain homologous constituents. Echinoidea and Ophiuroidea contain different constituents which are themselves homologous. From these considerations it appears that the Asteroidea and Holothuroidea are more closely related to each other phylogenetically than to the Echinoidea, or the Ophiuroidea, while the latter two classes are also related to each other.

Table 1. DISTRIBUTION OF STEROLS, BATYL ALCOHOL AND PHOSPHAGENS AMONG THE CLASSES OF ECHINODERMS

Class	Arginine phosphoric acid	Creatine phosphoric acid	$\Delta^5$ sterols	$\Delta^7$ sterols	Batyl alcohol†
Crinoidea	+	—	+	—	+
Asteroidea	+	—	—	+	±
Holothuroidea	+	—	—	+	+
Echinoidea	+	+	+	—	—
Ophiuroidea	—	+	+	—	—

† Determined by titration with periodic acid<sup>4</sup>. The sign ± for the Asteroidea is intended to indicate that three of the nine species examined contained a small enough amount of batyl alcohol to make its presence questionable. One ophiuroid may have contained a small quantity of batyl alcohol.

This conclusion lends support to well known embryological evidence<sup>12</sup> that the first larval form (Dipleurula) in the development of the echinoderm is common to four classes, while the later larvae take the forms outlined in Fig. 1. From the recapitulation theory this evidence leads to the same conclusions as comparative biochemistry.

Fell, having previously classed this application of the recapitulation theory as a "reductio ad absurdum" in the case of the echinoderms<sup>13</sup>, more recently described the inferred relationships as "too preposterous to warrant further serious consideration"<sup>1</sup>. Nevertheless, he acknowledged that most authors of zoological texts have accepted the views of embryologists.

\* Up to now, the only other groups of animals found to contain  $\Delta^7$ -sterols are sponges of the genus *Chondrilla*.

Fig. 1. Embryological development of echinoderms.

When a mass of evidence from anatomy and palaeontology is contradicted only by embryological evidence, it may indeed be permissible to dismiss the latter as "clandestine evolution, in response to temporarily planktonic food-gathering phases in the life history". When the reasoning from embryology receives independent support from a second, entirely different, type of scientific evidence, however, they cannot both be so easily turned aside. It is clear that biologists must reconsider their views of the phylogeny of the echinoderms. It should be remembered that the comparative biochemistry of sterols has already rendered useful service in revision of the taxonomy of some sponges<sup>4</sup>.

Returning now to Table 1, it is clear that the Crinoidea fall into a class by themselves, because they contain batyl alcohol and arginine phosphate, and  $\Delta^5$  rather than  $\Delta^7$  sterols. In fact, the one crinoid sterol, crinosterol, for which a reasonable structure has been proposed<sup>14</sup> is completely different from any other sterol of the animal or plant kingdoms. This suggests that the crinoids may have followed an entirely different line of evolution from the other echinoderms, just as they are believed to exhibit independent development beyond the Dipleurula stage.

The place of somasteroids in this scheme may well be clarified by a study of their chemistry.

### Crinosterol: a Unique Sterol from a Comatulid Crinoid

THE discussion of the ancestry of the sea-stars<sup>1,2</sup> has prompted me to review work I did some 15 years ago<sup>3</sup> on a biochemical aspect of the problem<sup>4,5</sup>. In that work I isolated from a species of *Comatula* (a crinoid) a sterol of unique properties, and believed it to be unknown at that time; I assigned it the name crinosterol<sup>5</sup>. These results have not, however, been published until now because the structure deduced from physical properties was the same

as that accepted for a known sterol, chalinasterol, and the conflict could not be resolved. Since then, the structure of chalinasterol has been reformulated, and established as 24-methylenecholesterol<sup>6</sup>. Thus it is now possible to suggest that crinosterol has the structure originally proposed.

The crinoid from which the sterol was extracted was obtained by Dr. W. Bergmann in 1950 from Dr. René Catala of Noumea, New Caledonia. The species was not definitely identified, but there is little doubt that it was a member of the genus *Comatula*.

From 800 g of specimen dried in air, extraction with acetone yielded 11.6 g of lipid, and hydrolysis of the fat in potassium hydroxide solution gave 3.39 g of unsaponifiable material, of which 1.18 g crystallized from methanol as crude sterol. Without further purification, the crude sterol was acetylated directly with acetic anhydride, and the acetate was recrystallized six times from absolute ethanol and twice from acetone to yield 128 mg, which melted at 144°–145°. One recrystallization from ether raised the melting point to 146°–147°,  $[\alpha]_D^{24} - 47.2^\circ$  (26.2 mg,  $\alpha = 0.40^\circ$ ), and the melting point did not change on further recrystallization. The elementary analysis gave: carbon, 81.40, and hydrogen, 11.14 per cent; the calculated results for the compound  $C_{30}H_{48}O_2$  are carbon, 81.76; hydrogen, 10.98 per cent. Hydrolysis of the acetate in 20 per cent potassium hydroxide in methanol (2 h on steam bath), and recrystallization of the product, twice from methanol and once from acetone, yielded the free sterol, which melted at 137°–138° (unaltered by further recrystallization),  $[\alpha]_D^{20} - 47.2^\circ$  (24.9 mg,  $\alpha = 0.38^\circ$ ). The free sterol was converted to its benzoate using benzoyl chloride in pyridine at room temperature. The benzoate, recrystallized first from chloroform-methanol, then five times from absolute ethanol, had a double melting point: it melted first at 135°, resolidified (with fluorescence), then melted again at 141°–143°. The elementary analysis gave carbon, 83.01; hydrogen, 10.12; calculated for  $C_{33}H_{50}O_2$ : carbon, 83.61; hydrogen, 10.03.

A sample of crude acetate (263 mg), melting at 116°–124°, was dissolved in ether, and brominated by adding a 5 per cent solution of bromine in glacial acetic acid. The product required extensive purification, and the final yield of tetrabromide, melting point 185°–186°, was only 10.8 mg; elementary analysis showed 43.25 per cent bromine; the calculated percentage of bromine for  $C_{30}H_{48}Br_4O_2$  is 42.04. The authenticity of this tetrabromide as a derivative of crinosterol acetate and not of some impurity was established by debromination with zinc and acetic acid. The debrominated compound, after one recrystallization from methanol, melted at 144°–146°, and an admixture with the crinosterol acetate described here melted at 145°–146°.

The quantities of pure materials isolated precluded the application of rigorous methods of determination of structure. The results of bromination, however, clearly established the presence of two double-bonds. That one of them was at C-5 could readily be deduced from the molecular rotations of the sterol, acetate, and benzoate<sup>7-9</sup>:  $[M]_{\text{acetate}} - [M]_{\text{sterol}} = -20$ , and  $[M]_{\text{benzoate}} - [M]_{\text{sterol}} = +98$ . Further consideration of molecular rotation differences showed that the only alterations of the structure of cholesterol which could logically account for them were a double bond at C-22 and a 24 $\beta$ -methyl group. While the possibility of a 24-ethyl group could not be eliminated on these grounds alone, its presence would require that the sterol be identical with stigmasterol (melting point 170°, ref. 5) or poriferasterol (melting point 156°, ref. 5). It is therefore proposed that crinosterol is the C-24 epimer of brassicasterol, and is 24 $\beta$ -methyl-22-dehydrocholesterol.

The crinoids *Antedon rosacea* and *Cenocrinus asteria* also yielded laevorotatory sterols, with acetates melting at 120°–122°,  $[\alpha]_D - 41.1^\circ$ . The sterol acetate from *C. asteria* gave a crystalline tetrabromide, melting point

180°. These sterols were probably not crinosterol, but insufficient material was available for further study.

### Formation and Destruction of Pyrimidine Dimers in Polynucleotides by Ultra-violet Irradiation in the Presence of Proflavine

THE ultra-violet irradiation of polynucleotides in solution results in the reversible formation of dimers of *cyclobutane* type between adjacent pyrimidine residues<sup>1</sup>. In DNA, such dimers produce important effects in many biological systems<sup>2</sup>. Beukers has also found that the presence of proflavine during irradiation at 2537 Å inhibits the formation of thymine dimers in DNA and that dimers produced in the absence of proflavine are destroyed by further irradiation in its presence<sup>3</sup>. Although Beukers was unable to show that the destruction of the dimers in DNA consists of a simple reversion to monomers, he suggested that this might be demonstrated by means of experiments with organized polymer dI-dC consisting of strands of polydeoxyinosinic acid and polydeoxycytidylic acid. Such a polymer has already been used to show that the enzymatic destruction of uracil dimers by photo-reactivating enzyme in the presence of visible light consists of monomerization<sup>4</sup>.

We have followed Beukers's suggestion, and have obtained data which indicate that his hypothetical scheme is correct. Our data indicate that proflavine affects only the rate of formation of dimers and not their monomerization. It follows that the steady state concentration of dimers, which depends on the balance of the forward and backward reactions, is altered by the presence of proflavine. By using proflavine to inhibit the formation of dimers, we have been able to measure the monomerization of dimers in DNA at several different wavelengths and have shown that at long wavelengths dimers containing cytosine may be selectively split by radiation in the presence of proflavine. The biological analogue of this finding is reported in an accompanying note<sup>5</sup>. Because the quantum yield for dimer formation in DNA is small<sup>6</sup> (approximately 0.01), any slight change in the configuration of DNA would be expected to alter this value drastically. Changes in DNA structure on binding of the dye molecules<sup>6,7</sup> are therefore sufficient to explain the results, and energy transfer mechanisms do not have to be invoked.

Monochromatic radiation was obtained by the use of a mercury arc and a large quartz prism monochromator. The radiant fluxes are computed as averages from the incident flux and the measured absorbance<sup>8</sup>. We investigated the polymers <sup>3</sup>H-cytosine-labelled dI-dC (40,000 c.p.m./μg) and tritium thymine labelled *E. coli* DNA (300,000 c.p.m./μg). Irradiation was carried out as described previously<sup>9</sup> in the presence of proflavine and under conditions in which polynucleotide and dye bind strongly together<sup>10</sup>. After irradiation, the solutions containing buffer, dye and polymers were heated and dried

Table 1. THE PERCENTAGES OF TOTAL RADIOACTIVITY IN URACIL DIMERS (UU) AND URACIL (U) AFTER ACID HYDROLYSIS OF <sup>3</sup>H-CYTOSINE-LABELLED dI-dC IRRADIATED IN THE ABSENCE OR PRESENCE OF PROFLAVINE (PRO)

Experiment	Wave-length Å	Flux erg mm <sup>-2</sup> × 10 <sup>-4</sup>	PRO absent		PRO present	
			UU	U	UU	U
(per cent activity)

	2390	1	7.0	4.3	6.9	4.7

Samples (0.2 ml.) had the following concentrations: polymer (in terms of nucleotides)— $1.6 \times 10^{-4}$  molar; proflavine— $1.8 \times 10^{-5}$ ; buffer—0.05 molar phosphate pH 7.0.

and the residues hydrolysed with 98 per cent formic acid. Radioactivity in dimers and thymine was assayed by paper chromatography followed by scintillation counting<sup>9,11</sup>. The dimers detected with dI-dC were uracil dimers—the deamination products of cytosine dimers. With DNA we detected thymine-thymine and uracil-thymine dimers—the deamination products of cytosine-thymine dimers. The presence of proflavine did not affect the hydrolysis, chromatography or counting efficiency.

Fig. 1. The effect of proflavine on the formation of dimers in DNA. *E. coli* DNA labelled with <sup>3</sup>H-thymine was irradiated with 2800 Å radiation in the absence (○, □) and the presence (●, ■) of proflavine and was then analysed for the percentage of radioactivity in thymine-thymine (TT) and cytosine-thymine (CT) dimers. Samples of 0.2 ml. of 0.01 M phosphate buffer pH 7.0 contained 1.2 μg/ml. of DNA and  $1.5 \times 10^{-5}$  M proflavine. The radiation flux is corrected for absorption by the dye.

Table 1 presents data from three types of experiments on the effects of proflavine on dimer formation and destruction in dI-dC. Experiment A indicates that the presence of proflavine inhibits dimer formation in this polymer. (The uracil that does appear is largely the result of deamination of cytosine during acid hydrolysis and not of irradiation<sup>9</sup>.) Experiment B shows that short wavelength (2390 Å) radiation can reverse the effects of long wavelengths and that dimers once formed may be destroyed in the presence of proflavine by further irradiation at 2800 Å. The destruction of dimers by short wavelengths is the more complete in the presence of proflavine.

When irradiated dI-dC is heated, the cytosine dimers deaminate to form uracil dimers, which have small absorption coefficients at long wavelengths and which are therefore not monomerized by such radiation. Experiment C illustrates the effects of further irradiation on dI-dC already containing uracil dimers. A large dose at a long wavelength has practically no effect, whereas at short wavelengths there is a significant decrease in uracil dimers and an equal increase in the amount of uracil produced both with and without proflavine. Thus the destruction of uracil dimers consists of monomerization, and this process is not affected by the presence of proflavine. These data support Beukers's description<sup>3</sup>.

The results of the experiments with DNA are given in Fig. 1, which shows that the presence of proflavine during irradiation at 2800 Å inhibits the formation of both thymine-thymine and cytosine-thymine dimers, and that there is a ten-fold decrease of dimer formation. The data in Fig. 2 indicate that for DNA as for dI-dC (Table 1) there is a large net destruction of cytosine dimers with continued irradiation at long wavelengths in the presence of proflavine. Thus irradiation at 2800 Å selectively destroys dimers containing cytosine, but thymine-thymine dimers are relatively unaffected because of their extremely low absorption coefficient at this wavelength. At shorter wavelengths (2650 Å and 2390 Å), both thymine-thymine and cytosine dimers are destroyed.

At 2390 Å the initial rate of monomerization of dimers in DNA is independent of the presence of proflavine. Moreover, in the presence of proflavine, the destruction of dimers as a function of wavelength is not qualitatively similar to the absorption spectrum of the dye, which is a maximum at 2600 Å. Thus, energy transfer mechanisms do not play an important part in dimer destruction in the presence of proflavine, and the best description of the effects of proflavine on dimer formation and monomerization in DNA is that the dye inhibits only the formation of dimers and does not affect their monomerization.

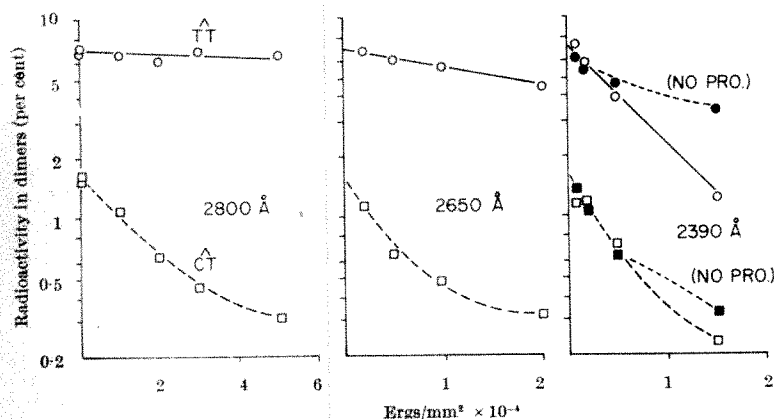

Fig. 2. The destruction of thymine-thymine and cytosine-thymine dimers by three different wavelengths of ultra-violet light in the presence of proflavine (pro) and at 2390 Å in its absence (no pro). *E. coli* DNA at 1.2 µg/ml. in 0.01 molar phosphate buffer pH 7.0 and labelled with <sup>3</sup>H-thymine was first irradiated at 2800 Å with  $3 \times 10^4$  erg/mm<sup>2</sup>. Proflavine was then added to a concentration of  $1.5 \times 10^{-5}$  molar, and irradiation was continued at the indicated wavelengths.

The finding that long wavelength irradiation in the presence of proflavine selectively monomerizes dimers containing cytosine has led to an estimate of the relative importance of cytosine dimers in the inactivation of transforming DNA (ref. 4). Because the net monomerization by short wavelengths is more extensive in the presence of proflavine, it may be possible to carry out reversal experiments on biologically active systems at much smaller initial doses than have been used so far.

We are indebted to R. Beukers for his helpful suggestions and advice and to F. J. Bollum, of the University of Kentucky, for his gift of dI-dC. This research was sup-

ported by the U.S. Atomic Energy Commission under contract with the Union Carbide Corporation.

### Contribution of Dimers containing Cytosine to Ultra-violet Inactivation of Transforming DNA

BEUKERS<sup>1</sup> has shown that dimers containing thymine in DNA irradiated at 2537 Å can be eliminated by further irradiation at 2537 Å in the presence of proflavine, and later work<sup>2</sup> has confirmed his hypothesis that the elimination represents splitting of the dimers. We have shown that the biological inactivation of ultra-violet-irradiated transforming DNA from *Haemophilus influenzae* may similarly be reversed by irradiation in solutions containing proflavine. An investigation of the wavelength dependence of this reactivation in the presence of proflavine, together with information on the reversal of different types of pyrimidine dimers<sup>3</sup>, has made it possible to evaluate the role of dimers containing cytosine in inactivation.

Ultra-violet irradiation and the transformation assay were done as previously described<sup>4</sup>. The incident doses were corrected for absorption by the solutions. For irradiation, transforming DNA at room temperature was in 0.01 M phosphate buffer, pH 7, at a concentration of 1 µg/ml. Proflavine was used at a final concentration of 5–6 µg/ml. After a 30-fold dilution, the DNA was assayed for ability to transform *H. influenzae* cells to resistance to 2.5 µg/ml. cathomycin. Under these conditions proflavine did not itself affect the number of transformants.

Fig. 1 shows that transforming DNA inactivated to 1 per cent survival by 2520 Å radiation is reactivated by further irradiation at the same wavelength after proflavine has been added to the solution. Proflavine also protects transforming DNA from inactivation when it is present during irradiation, as shown in Fig. 2, and as previously shown by Beukers<sup>1</sup> and by Lerman<sup>4</sup> for acridine orange. The data are presented on a square root plot<sup>5</sup>, which gives a straight line for inactivation in the presence and in the absence of proflavine. It is seen in Fig. 2 that the ratio of the sensitivities for the inactivation of *H. influenzae* transforming DNA by 2800 Å radiation with and without proflavine is 10.8, close to the value of 10 observed under similar experimental conditions for the ratio of the numbers of dimers containing thymine in *E. coli* DNA irradiated with and without proflavine. These data provide additional evidence for the importance of dimers in inactivation.

We have previously shown that transforming DNA exposed to a large dose at long wavelength may be reactivated by subsequent irradiation at short wavelength<sup>6</sup>. Fig. 3 shows that the amount of reactivation is greater when proflavine is present during the short-wavelength irradiation. Similar results have been found for elimination of dimers by short-wavelength irradiation with and without proflavine<sup>2</sup>. Proflavine appears not to alter the initial rate of the reaction but rather the final level. Thus proflavine does not affect the probability of dimer splitting but apparently decreases the probability of the dimerization reaction.

The amount of reactivation by 2650 Å radiation in the presence of proflavine following 2800 Å inactivation is intermediate between the large reactivation produced by 2390 Å radiation and the small reactivation at 2800 Å. This wavelength dependence is not similar to the absorption spectrum of proflavine, which peaks at 2600 Å and drops markedly on either side of the peak, but is similar to that of pyrimidine dimers<sup>7</sup>, suggesting that energy for reactivation is absorbed in pyrimidine dimers rather than in the dye itself.

Fig. 4 shows the reactivation of transforming DNA in the presence of proflavine by 2800 Å radiation following

Fig. 3. Short-wavelength reactivation of *H. influenzae* transforming DNA with and without proflavine present. The DNA was first irradiated at 2800 Å without proflavine, and then at 2390 Å either with or without proflavine.

Fig. 1. Reactivation of *H. influenzae* transforming DNA inactivated by 2520 Å radiation by further irradiation in the presence of proflavine.

Fig. 4. Reactivation at 2800 Å of *H. influenzae* transforming DNA inactivated at the same wavelength by a dose of  $8 \times 10^4$  ergs/mm<sup>2</sup>. After maximum reactivation, the survival of transforming DNA was the same as the survival after an initial dose of  $2 \times 10^4$  ergs/mm<sup>2</sup>. Thirty-three per cent of the biological damage has therefore been eliminated.

Fig. 2. Inactivation of *H. influenzae* transforming DNA with and without proflavine in the solution of DNA. The numbers of transformants produced by unirradiated and irradiated DNA are  $N_0$  and  $N$ , respectively.

inactivation by the same wavelength without proflavine. The amount of reactivation is small but significant. At this wavelength there is a clear differential effect of irradiation in the presence of proflavine on thymine-thymine and cytosine-thymine dimers, in that there is negligible splitting of thymine-thymine dimers<sup>2</sup>. From the data of several experiments similar to that shown in Fig. 4, we have determined that between 14 and 33 per cent of the biological damage produced by 2800 Å radiation can be removed by irradiation at 2800 Å in the presence of proflavine. We estimate from data for *E. coli* DNA that in *H. influenzae* DNA under the same experimental conditions, 20 per cent of the total dimers are split, of which no more than 4 per cent are thymine-thymine dimers<sup>2</sup>. Because there are very few cytosine-cytosine dimers in *H. influenzae* DNA<sup>7</sup>, cytosine-thymine dimer splitting must therefore account for almost all the biological effect shown in Fig. 4. Furthermore, the correspondence between the fraction of biological damage removed and the percentage of total dimers eliminated—as measured by ultra-violet absorbance<sup>6</sup>—suggests that cytosine-thymine and thymine-thymine dimers are similar in their contribution to inactivation.

### *cis-syn* Thymine Homodimer from Ultra-violet Irradiated Calf Thymus DNA

THE present interest in the ultra-violet irradiation of nucleic acids<sup>1-3</sup> seems to warrant the tedious effort required to isolate in small quantities and to identify the product(s) formed in biological material, at doses compatible with biological assays of the radiation-induced damage.

The appearance of two areas of radioactivity on paper chromatograms of the acid hydrolysates of DNA labelled with thymine and irradiated with ultra-violet light was recently reported by Boyce and Howard-Flanders<sup>4</sup> and by Riklis<sup>5</sup>. The eluent used was *n*-butanol-acetic acid-water (80:12:30; v/v). Other eluents were also shown to give good separations<sup>6</sup> in a study of the chemical nature of these products from irradiated DNA. On the basis of these findings, a reliable procedure was established for obtaining these products not only in high purity but also in quantities large enough to allow the elucidation of structure using ultra-violet, nuclear magnetic resonance, and infra-red spectra. In this communication, we wish to report the identification of the *cis-syn* thymine homodimer (T=T)<sup>7</sup> as one of these products.

Native calf thymus DNA (5 g for each run) was dissolved at a concentration of about 60 µg/ml. (O.D. 1.2 at the maximum) in 0.15 molar sodium chloride solution.

The DNA solution was irradiated in enamel pans (40 × 25 cm), and 750-ml. portions of the dilute solution

Fig. 1. Ultra-violet absorption spectra of *a*, *cis-syn* thymine homodimer from acid hydrolysates of ultra-violet irradiated DNA, and *b* after 10 min irradiation in aqueous solution.

Fig. 2. Nuclear magnetic resonance spectrum of *cis-syn* thymine homodimer isolated from ultra-violet irradiated DNA. Solvent is CF<sub>3</sub>COOD. Values of δ are shown in p.p.m. from tetramethylsilane.

were irradiated for 25 min with a total dose of  $5 \times 10^4$  ergs/mm<sup>2</sup>. The choice of this irradiation condition was based on a time study which indicated that under these conditions irradiated DNA gives optimal competitive inhibition of the photoenzymatic reactivation of irradiated transforming DNA<sup>8</sup>.

The irradiated solution (72 l. per run) was concentrated to 10 l. and dialysed overnight against a continuous flow of water. The dialysed solution was concentrated to dryness.

The completely dried sample was taken up in about 200 ml. of trifluoroacetic acid (TFA), and then transferred to and sealed in twenty 'Pyrex' glass tubes with heavy walls. These were heated at 170°C for 90 min. The hydrolysate was filtered to remove some insoluble material. Both the tubes and the residue were washed twice with 0.1 normal hydrochloric acid. After the filtrates had been evaporated to dryness, the residue was dissolved in about 75 ml. of TFA.

The hydrolysates in TFA were then spotted on twenty-five sheets of Whatman No. 3 paper (57 × 13.5 cm), and developed with *n*-butanol-acetic acid-water for 20 h by the descending technique. The areas between *R<sub>F</sub>* 0.15 and 0.35 of the dried chromatograms were cut out and extracted three times with 500 ml. of 0.1 normal hydrochloric acid. In order to determine whether the extraction was complete, spectra were taken for each sample before and after irradiation. The extract of hydrochloric acid was evaporated to dryness and subjected to rechromatography several times using different solvent systems. The chromatography procedure used was similar to that already described; the conditions and data are summarized in Table 1.

Table 1

Chromatography	Residue dissolved in 0.1 normal hydrochloric acid (ml.)	Sheets of paper	Eluent* (time, h)	Area cut-out ( <i>R<sub>F</sub></i> )	Extract in 0.1 normal hydrochloric acid (ml.)
Second	15	8	A (20)	0.29	3 × 200
Third	8	4	B (23)	0.54	3 × 150
Fourth	5	2	C (20)	0.15	3 × 100

\* Solvent systems: A, *n*-butanol-acetic acid-water (80:12:30); B, isopropanol-concentrated hydrochloric acid-water (68:15.5:16.5); and C, *n*-butanol-water (86:14). (All proportions given by volume.)

In order to locate the desired areas on the chromatograms, DNA labelled with thymine-2-<sup>14</sup>C was used in parallel runs under identical conditions.

Four milligrams of a slightly yellow material, obtained by concentrating the final hydrochloric acid extract, was washed twice with 5 ml. of absolute ethanol to remove the colour.

Fig. 3. Infra-red spectrum of *cis-syn* thymine homodimer isolated from ultra-violet irradiated DNA.

The residue was dissolved in 25 ml. of hot water. The filtrate, concentrated to 3 ml., was allowed to stand in a refrigerator overnight. The colourless crystalline product which separated from water after two crystallizations gave ultra-violet, infra-red, and nuclear magnetic resonance spectra identical to those of the thymine homodimer obtained from frozen solutions.

Our experiments provide evidence that T=T is a product of DNA irradiated with ultra-violet light. According to a recent report<sup>9</sup> on the naturally abundant <sup>13</sup>CH satellite proton spectra of T=T, this product should have the *cis-syn* configuration. Because the isolation procedure involved acid hydrolysis, it has yet to be shown that T=T is a photo-product formed directly on irradiation. This is especially true because it has recently been shown that irradiation of cells in which the DNA contained thymine labelled at both the 2-carbon and 5-methyl hydrogen yielded T=T with a 30 per cent reduction in the ratio of <sup>3</sup>H/<sup>14</sup>C when compared with thymine<sup>6</sup>. Because direct formation of T=T does not involve the 5-methyl group<sup>8</sup>, it would appear that the formation of T=T on cellular DNA may involve at least one intermediate step.

On the basis of chromatographic mobility and photo-reversal to thymine in solution, it has been suggested<sup>10,11</sup> that T=T is the product formed when DNA is irradiated with ultra-violet light. In recent reports<sup>4,5</sup>, however, two chromatographically separable products were observed, and T=T was again assumed to be the principal product. Blackburn and Davies<sup>12</sup> have attempted to establish the structure of the product of irradiated DNA by using T=T from ice. Although this approach is interesting, we must emphasize that the so-called principal product consists of at least one other compound which is chromatographically indistinguishable and co-crystallizable with T=T although it is not T=T (unpublished results).

We thank Dr. R. M. Herriott for generously supplying the DNA, Denis LaCroix and Dr. C. S. Rupert for their study of the competitive inhibition, and Dr. D. P. Hollis for the nuclear magnetic resonance spectra. We also thank these colleagues and Drs. M. H. Patrick and L. Frank for valuable comments and suggestions.

### Influence of Protracted Infusion of Glucose and Insulin on the Composition and Regeneration Activity of Liver after Partial Hepatectomy in Rats

In the liver tissue which remains after partial hepatectomy (resection of 65–70 per cent of the liver) marked changes in the composition and the energy metabolism<sup>1,2</sup> develop even before the occurrence of increased mitotic activity. The energy metabolism in the liver tissue is shifted from a predominant utilization of glycides to an increased utilization of lipids<sup>3</sup> with a corresponding decrease in the content of glycogen and an increase in the content of lipids. We wished to find out whether the regenerative activity of the liver would be affected if the development of these changes was arrested.

The experiments were carried out on male rats weighing 200 g, which were fed on a standard laboratory diet until the operation<sup>4</sup>. In the experimental groups of rats (groups 2–4) partial hepatectomy was performed by the method of Higgins and Anderson<sup>5</sup>. Group 1 included normal rats in which the rest of the liver remaining after resection was analysed. After partial hepatectomy the rats of the second group were given an infusion of Ringer's solution, rats of the third group 20 per cent glucose (in Ringer's solution), rats of the fourth group 20 per cent glucose solution containing 0.02  $\mu$  of crystalline insulin (*SPOFA*) per 1 ml. The infusion apparatus administered the solutions into the left jugular vein of the rats each hour for 5 min, the dose being 0.3 ml./100 g body weight. Thirty-four hours after the operation the rats were killed by decapitation. Two hours before death

Table 1. WEIGHT OF LIVER REMAINING AFTER PARTIAL HEPATECTOMY, DRY TISSUE AND COMPOSITION, BEFORE AND AFTER INFUSION OF RINGER'S SOLUTION, 20 PER CENT GLUCOSE OR 20 PER CENT GLUCOSE WITH INSULIN

	Before infusion (control values)	After infusion—36 h after partial hepatectomy		
		Ringer's solution	20 per cent glucose	Insulin and 20 per cent glucose
Weight of the liver g/100 g body weight	1.40 $\pm$ 0.36	2.10 $\pm$ 0.28 <0.001	2.18 $\pm$ 0.38 <0.01	1.70 $\pm$ 0.24 <0.05
Dry liver tissue (per cent)	31.6 $\pm$ 1.18	32.5 $\pm$ 2.03	33.1 $\pm$ 2.71	29.3 $\pm$ 1.66
Lipids	56.0 $\pm$ 18.2	222.0 $\pm$ 40.6 <0.001	205.0 $\pm$ 18.6 <0.001	104.0 $\pm$ 20.4 <0.001
Protein nitrogen	15.6 $\pm$ 3.64	24.3 $\pm$ 4.69 <0.01	26.8 $\pm$ 5.47 <0.01	17.8 $\pm$ 2.00
Ribonucleic acids	11.2 $\pm$ 1.36	17.6 $\pm$ 2.80 <0.001	20.4 $\pm$ 1.56 <0.001	15.7 $\pm$ 2.50 <0.01
Deoxyribonucleic acids	4.1 $\pm$ 0.37	6.3 $\pm$ 1.15 <0.001	6.8 $\pm$ 2.15 <0.01	4.3 $\pm$ 0.86

Infusions were started immediately after partial hepatectomy.

tritiated thymidine (200 mc./0.4 ml./200 g) with a specific activity of 6.0 c./mmole was injected into the femoral vein of each rat. Incorporation of thymidine-<sup>3</sup>H into the nuclei of the liver cells was monitored by the autoradiographic method<sup>6</sup>. In liver sections stained with iron haematoxylin, the mitotic index (number of mitoses found in 1,000 nuclei of parenchymal liver cells) was ascertained. The content of lipids<sup>7</sup>, nucleic acids<sup>8</sup>, and protein nitrogen<sup>9</sup> was determined in the samples of liver tissue. The results were evaluated statistically using Student's *t* test.

Fig. 1. Mitotic index of parenchymal liver cells (per cent; white columns) and number of nuclei in these cells labelled by thymidine-<sup>3</sup>H (per cent; <sup>3</sup>H-index; black columns) in rats with intact livers (C), and in rats with partial hepatectomy following infusion of Ringer's solution (R), 20 per cent glucose (G) or 20 per cent glucose with insulin (G+I). Standard deviations are mentioned with the average values.

Thirty-four hours after partial hepatectomy there was a smaller increase in the weight of the liver which remained after resection and also a smaller total amount of lipids, protein nitrogen, RNA and DNA in the liver tissue of rats which were injected with the solution of insulin and glucose (Table 1). The values of the mitotic index were considerably lower ( $p < 0.001$ ) in the rats into which solutions of insulin and glucose were infused than in the rats of the other experimental groups (Fig. 1). The number of nuclei of parenchymal liver cells labelled with thymidine-<sup>3</sup>H also decreased in the group of rats which had been infused with insulin and glucose as compared with the rats which were infused with Ringer's solution ( $p < 0.001$ ) or glucose solution alone ( $p < 0.01$ ) (Fig. 1). Insulin administered in the infusion with glucose increases lipogenesis, especially in the adipose tissue, and at the same time inhibits liberation of free fatty acids from this tissue<sup>10,11</sup>. The slackening of the growth of the lipid content in the liver is probably connected with the limited mobilization of free fatty acids from the fat deposits which usually occur after partial hepatectomy. This shift in liver lipid content has also been confirmed by our recent, still unpublished experiments, in which the mobilization of free fatty acid after partial hepatectomy was partially blocked by hexamethonium or nicotinic acid. It is well known that the liver takes up free fatty acid from the blood, in a similar way as the heart or the skeletal muscles, for example in dependence on their concentration in the blood. After partial hepatectomy the increased supply of free fatty acid to the liver leads to an increased lipid content in the liver simultaneously, however, with an increased utilization of this substance<sup>2,3</sup>. This shift in the energy metabolism secures the necessary energy for the liver tissue being under the condition of an increased functional strain in which a regenerative process characterized by a predominance of endergonic reactions is just going on. We believe that as a consequence of the partial inhibition of the growth of lipids in the liver a shift of the metabolism of the liver takes place. We suppose that the decrease in the regenerating activity of

the liver observed by us is probably also connected with the inhibited development of these changes.

### Catabolism of Tryptophan by the Isolated, Perfused Liver and Intestine

THE metabolism of tryptophan has received considerable attention from biochemists<sup>1,2</sup> and has been of particular interest because a number of physiologically active agents, such as serotonin, are among the many metabolites of tryptophan. Information about tryptophan metabolites is extensive in a qualitative sense, but quantitative data on tryptophan catabolism in various organs are scarce. The present communication deals with certain quantitative aspects of tryptophan metabolism in the perfused liver and intestine of the rat.

The perfusion of the isolated liver or intestine of the rat was performed by the Miller technique<sup>3</sup> as described in an earlier communication<sup>4</sup>. Forty millilitres of fresh, heparinized rat blood diluted with one third of its volume of Ringer's solution (Fixanal Ringer-Riedel de Haën) and containing 200 mg of glucose was used as perfusion fluid. In the tryptophan loading experiment 50  $\mu$ moles of unlabelled L-tryptophan was added to the perfusion fluid. The animals were maintained on a standard diet (A.M. and R.M.H. 1/1 from Kray—Oost-Knollendam—Holland) which contained all important vitamins including 6.5 mg/kg of pyridoxine. The animals were starved from 18 h before perfusion.

Tryptophan labelled with tritium primarily in the aromatic ring (more than 75 per cent of total activity of tritium) and with carbon-14 in carbon atom 2 of the indole ring was used in all these experiments. Tritiated L-tryptophan had a specific activity of 136 mc./mmole whereas DL-tryptophan (indolyl-2-<sup>14</sup>C) had a specific activity of 5.2 mc./mmole. The purity of the compounds was ascertained by paper chromatography in two solvent systems. Only one peak coinciding with authentic tryptophan was seen.

The labelled material was added to the perfusate at the beginning of the experiments and samples of perfusate and organ tissue, bile in the case of the liver, and carbon dioxide were obtained at various times during the perfusion. Carbon dioxide was collected in ethanolamine and methyl cellosolve (1:2). Samples of perfusate, and homogenates of liver and intestine prepared by homogenization with a pestle after addition of four volumes of water, were treated with one volume of acetone. The resulting precipitate was removed by centrifugation and the supernatant used for the determination of carbon-14 and tritium activity as well as of the concentration of tryptophan. The radioactivity of carbon-14 and tritium was determined by liquid scintillation spectrometry

using a Packard Tri-carb apparatus. Tryptophan concentration was determined by the fluorometric method of Duggan and Udenfriend<sup>5</sup>. Labelled carbon dioxide and the radioactivity in bile were determined in aliquots of the collected material without further treatment.

Data on radioactivity in liver, perfusate and bile expressed in percentage of the total radioactivity initially added to the perfusate are presented in Fig. 1. Perfusions were carried out either at physiological concentrations of tryptophan (4  $\mu$ moles) or in conditions of tryptophan loading after addition of 50  $\mu$ moles of L-tryptophan to the perfusion fluid. Pertinent data on the specific activities of tryptophan and the concentration of tryptophan during perfusion are also shown. The use of the DL-form of tryptophan labelled with carbon-14 introduces certain difficulties in interpreting the changes with time, particularly in the perfusion experiment involving physiological concentrations of tryptophan in the perfusion fluid. Evidence reported in the literature<sup>2</sup> indicates that D-tryptophan is metabolized at one half of the rate of L-tryptophan in liver slices. This finding may explain the slower rate of decrease in activity of carbon-14 as compared with that of activity of tritium in the perfusion carried out at physiological concentrations of tryptophan. This effect is not noticeable in the perfusion in conditions of loading, presumably because of the presence of massive amounts of L-tryptophan.

When tryptophan (indolyl-2-<sup>14</sup>C) is used, it is clear that all of the activity of carbon-14 is lost in the metabolic step in which *N*-formyl kynurenine is converted to kynurenine. Metabolic labilization of tritium in the tritium-labelled tryptophan used in these experiments can,

Fig. 1. Catabolism of 4 or 50  $\mu$ moles of tryptophan (mixture of tritiated benzene and <sup>14</sup>C-2-indolyltryptophan) in the isolated perfused liver. The curves for radioactivity of tryptophan decrease only slightly more rapidly than those for non-volatile tritium activity. ○, Carbon-14 in perfusate; ●, non-volatile tritium in perfusate; □, carbon-14 in liver; ■, non-volatile tritium in liver; +, tryptophan concentration in perfusate; ×, tryptophan concentration in liver; +, tritium in bile; ▲, tryptophan specific activity.

Fig. 2. Catabolism of 4  $\mu$ moles of tryptophan (mixture of tritiated benzene and <sup>14</sup>C-2-indolyltryptophan) in the isolated perfused intestine. There is no significant difference between values for carbon-14 and tritium and no volatile activity is found. ●, Total activity, and ○, tryptophan activity in perfusate; ■, total activity, and □, tryptophan activity in intestine; +, tryptophan concentration in intestine; ×, tryptophan concentration in perfusate; ▲, tryptophan specific activity in perfusate; △, tryptophan specific activity in intestine.

however, be expected during the formation and further degradation of 3-hydroxyanthranilic acid and should result in the formation of tritium oxide, thus enriching the body water with tritium. Catabolism of tryptophan occurs rapidly (Fig. 1), primarily by way of the kynurenine pathway, and results in the formation of compounds devoid of carbon-14. Only a small fraction (about 10 per cent), however, of the total activity of carbon-14 added to the perfusate is found in labelled carbon dioxide at the end of a 2 h perfusion. On the assumption that some of the activity of carbon-14 can enter the pool of the "one-carbon fragment", certain amino-acid residues in liver-protein isolated from perfused livers have been examined. It was found that about 20 per cent to 30 per cent of the total activity of carbon-14 was present in protein bound serine and alanine after 2 h of perfusion. On the other hand, chromatography of the acetone soluble fraction of blood and liver revealed the presence of only small quantities of radioactive substances other than tryptophan, even in conditions of tryptophan loading.

Fig. 1 shows that substantial quantities of tryptophan metabolites are excreted into the bile, but some of these metabolites are devoid of carbon-14 and contain only tritium. One of the main products of excretions in the bile has been tentatively identified as 3-hydroxyanthranilic acid. Initially, tryptophan disappears more slowly in conditions of tryptophan loading, but its catabolism increases as the perfusion progresses, probably as a result of the induction or activation of tryptophan pyrrolase<sup>6</sup> after the addition of the 50  $\mu$ moles of L-tryptophan.

The data presented in Fig. 2 demonstrate that the kynurenine pathway of tryptophan catabolism plays only a very small part in the intestine if this pathway exists at all in this organ. This conclusion is based on the finding that, in contrast to the finding in liver, there is

(a) no loss of carbon-14 and (b) no detectable formation of tritium oxide. The formation of at least one metabolite of tryptophan, however, was noted and it was tentatively identified as indole acetic acid.

### Connective Tissue and the Pentose Phosphate Pathway in Normal and Denervated Muscle

DIRECT oxidation of glucose-6-phosphate through the pentose phosphate pathway is known to occur in various animal tissues. The enzymes glucose-6-phosphate dehydrogenase (G6PDH) and 6-phosphogluconate dehydrogenase (6PGDH), which are involved in the first two steps of this pathway, have been found in many organs. The activity of these enzymes in skeletal muscle is exceptionally low compared with that of most other mammalian tissues studied<sup>1</sup>. Their activity does, however, increase in muscles undergoing atrophy. This increase appears to be relatively unspecific, as it has been observed in denervation atrophy, hereditary muscular dystrophy, muscle necrosis due to trauma or viral infection, and in myopathy induced by drugs<sup>2-4</sup>. We have studied the G6PDH and 6PGDH activity in normal and denervated soleus and gastrocnemius muscles of the rabbit. Our findings suggest that the increase in activity of these enzymes may be the result, not of specific changes in the muscle cell itself, but rather a reflexion of the increase in connective tissue.

Adult male albino rabbits underwent transection of one sciatic nerve. Their soleus and gastrocnemius muscles were removed 2, 4 and 8 weeks after denervation. The preparation of the specimens and the reference base used were the same as those indicated in a previous report<sup>5</sup>. G6PDH and 6PGDH were assayed according to Lowry *et al.*<sup>6</sup> except that the formation of NADPH was followed directly in a fluorometer. Collagen was estimated from the hydroxyproline content, measured by the method of Neuman and Logan<sup>7</sup> as modified by Martin and Axelrod<sup>8</sup>.

Fig. 1 shows the results obtained. Non-collagenous protein is used as reference base because it appears to be a good index of the functioning muscle mass<sup>5</sup>. Each point represents the mean value from six rabbits. All the differences between the controls and the denervated groups were significant at the level  $P=0.01$ . It can be seen that there are differences between both the enzyme and collagen content of the normal soleus and gastrocnemius. The enzyme activities and the amount of collagen per each unit of non-collagen protein were about three times higher for the soleus than for the gastrocnemius of unoperated animals. After denervation a gradual increase in these values occurred. After 8 weeks, all three values had risen about 2.5 times in the denervated soleus and 8.5 times in the gastrocnemius. Using the total fresh weight of each muscle as reference, an

increase in collagen could still be seen (Table 1). Thus, the elevation noted using protein as a reference base partly reflects an absolute increase in collagen. Similar results were obtained from an estimation of total enzyme activity. To rule out the loss of an inhibitor or the appearance of an activator, homogenates from control and denervated muscles were mixed in different proportions. The enzyme activity of the mixtures was that expected from simple addition.

Table 1. TOTAL COLLAGEN CONTENT OF THE MUSCLES STUDIED

Type of muscle	Control*	Denervated*		
		2 Weeks after denervation	4	8
Soleus	13.6 ± 0.8	13.3 ± 0.7	14.1 ± 1.5	17.2 ± 1.2
Gastrocnemius	51.2 ± 4.7	54.7 ± 5.1	59.8 ± 8.9	79.3 ± 9.1

\* Values ± standard errors of the mean expressed as mg collagen/entire muscle.  
†  $P < 0.05$ .

The differences found between normal soleus and gastrocnemius are not very surprising. These muscles are known to differ from one another not only functionally but also in their chemical composition<sup>9</sup>. The soleus is a tonic or slow muscle, mostly involved in postural regulation; the gastrocnemius is a phasic or fast one, mainly used in voluntary movements.

This parallelism between the activities of G6PDH and 6PGDH and the content of collagen is remarkable. It suggests that connective tissue, the source of collagen, is responsible for the presence of these enzymes in muscle homogenates. Thus the elevation of their activity observed in a variety of muscle disorders would reflect the increase of connective tissue in the affected muscles. Direct evidence for this would only be possible by histochemical methods. Localization of these enzymes using histochemical techniques is, however, difficult as they are soluble<sup>1</sup> and tend to diffuse rapidly. Supportive evidence of an indirect nature can be found in a study by Woessner and Boucek<sup>9</sup>. They measured the enzyme concentrations of rat connective tissues on implanted polyvinyl sponge. The activities of G6PDH and 6PGDH that they reported were twenty to forty times greater for this tissue than those found in rat skeletal muscle by numerous authors using a variety of assay methods<sup>1,10</sup>. A similar relationship may exist between connective tissue increase and the elevation of some hydrolytic enzymes in diseased muscle. Acid phosphatase and 5-nucleotidase, both high in sponge connective tissue<sup>9</sup>, are increased in homogenates of denervated and dystrophic muscles<sup>2,3,11</sup>. Both enzymes

Fig. 1. Changes in enzyme activity and collagen content of soleus and gastrocnemius after denervation. G6PDH (■) and 6PGDH (●) activities are expressed in  $\mu\text{moles/h}$ , and collagen ( $\Delta$ ) in  $\text{grams} \times 2/3$  (the fraction is introduced as a factor to make the curves more readily comparable).

have been found mainly in the proliferating connective tissue of dystrophic muscle<sup>12,13</sup>.

If, as our results suggest, the activity of the pentose phosphate pathway in muscle homogenates arises mostly from the connective tissue present in these, the possibility exists that connective tissue might have a hitherto unreported role in regeneration by furnishing some metabolites to the muscle cell. Pentose sugars are produced in this pathway. There is a parallel between the activity of the pentose shunt and the synthesis of RNA in normal tissues<sup>14</sup>. Although the activity of the pathway is low in muscle homogenates, it has been estimated by Hiatt and Lareau to be sufficient to furnish the ribose required for RNA synthesis in normal muscle<sup>15</sup>. This synthesis is probably increased in the regenerative processes that follow necrosis of muscle tissue. In such conditions the proliferation of connective tissue might fulfil the increased need of muscle fibres for some metabolites. If this were so, the question would arise as to how such metabolites would reach these fibres from the connective tissue cells. Fibroblasts apparently can release portions of their cytoplasm into the intercellular spaces by a mechanism comparable with that of apocrine secretion<sup>16</sup>. It is conceivable that ribose-5-phosphate might reach the intercellular space in this way and then enter the muscle cell after having been split by the phosphatases which are abundant in connective tissue.

At present, there is active research into the quantitative biochemical changes occurring in diseased organs. An increase in the activity of G6PDH and of some lysosomal enzymes is a relatively common occurrence in pathological tissues. It is unfortunate that there are not better means of determining whether some of these changes represent intracellular alterations or simply reflect a variation in the proportion of several cell populations. In this respect, studies of tissue using implanted sponges in different species, combined with an evaluation of the degree of proliferation of connective tissue in the organs under observation, might be helpful in cases where histochemical techniques do not provide an answer.

The part played by connective tissue in removing cellular debris and as a supporting matrix is well recognized. In addition, connective tissues may play an active part in the repair and regenerative processes of organs by furnishing some of the needed materials.

This investigation was supported in part by the National Foundation for Neuromuscular Diseases and by a grant from the U.S. National Institute of Neurological Diseases and Blindness.

## Phenylketonuria and Vitamin B<sub>6</sub> Function

THE essential role of vitamin B<sub>6</sub> (used as a group name to include pyridoxine, pyridoxal and pyridoxamine) in maintaining the proper function of the central nervous system has been established<sup>1</sup>. Mental retardation, hyperirritability, and convulsive seizures are manifestations of deficient vitamin B<sub>6</sub> metabolism. The similarity of the clinical syndrome of phenylketonuria suggests some malfunction of vitamin B<sub>6</sub>. Results of our studies on experimental phenylketonuria in rats indicate that inhibition of B<sub>6</sub> function contributes to the pathogenesis of phenylketonuria.

Recently we reported that exogenous phenylalanine and pyridoxine are precursors of a new metabolite (designated A) found in phenylketonuric urine but not in normal urine<sup>2</sup>. Metabolite A has been characterized as pyridoxylidene phenylethylamine. The question arises whether this compound interferes in some basic way with vitamin B<sub>6</sub> metabolism or whether synthesis of excessive amounts of it creates a deficiency of vitamin B<sub>6</sub> in the brain, thus causing mental derangement. Attempts to distinguish between these two possible mechanisms are described in this communication.

Experiments were conducted to determine whether the retarding effect of phenylalanine on learning in the rat<sup>3-5</sup> is influenced by pyridoxine in the diet, whether a deficiency of B<sub>6</sub> impairs learning, and whether phenylalanine affects recovery from B<sub>6</sub> deficiency symptoms.

Weanling male rats of the Holtzman strain were freely fed one of two diets: A, which contained an excess of pyridoxine, or B, from which pyridoxine was omitted. Three weeks later the animals on diet A were separated into four groups; 1 and 2 served as controls while 3 and 4 received phenylalanine. Rats fed diet B were also divided into four sets. Group 5 served as a control, while group 6 received phenylalanine. Groups 7 and C were fed the B<sub>6</sub> antagonist deoxypyridoxine<sup>6</sup> (DOP). When deficiency symptoms appeared in group C, the inhibitor was removed from the diet and recovery was observed under four dietary regimens (8-11) (see Table 1).

Table 1  
Composition of diet

	0 + DOP (5 mcg/g)	0	11
	0 + DOP (2.5 mcg/g)	0	10
C	0 + DOP (5 mcg/g)	0	11
	0 + DOP (2.5 mcg/g)	0	10

At the end of 3 weeks, B<sub>6</sub> deficiency symptoms had appeared in group C. Treatment with DOP was ended and the animals were maintained on diets 8-11 (Table 2).

Table 2

Diet B group	Pyridoxine (mcg/g)	L-Phenylalanine (mg/g)	Time fed (days)
8	100	0	18
9	100	70	18
10	0	0	18
11	0	70	18

Learning capacity was measured by counting errors made in the six channel maze (Fig. 1) during the log-phase of the learning curve (Fig. 2). Results shown in Table 3 established the validity of the water maze test to measure rate of learning.

Fig. 1. Swimming maze of stainless steel is similar to that described by Pilgrim *et al.*<sup>14</sup>. The tank is filled with water up to the level of the ramp, and the temperature is maintained at 15° C. To accustom the animals to water and to acquaint them with the openings and the exit ramp in the maze and to enable the investigator to weed out the inherently poor learners, a training period preceded the testing period. Throughout the training and testing periods the animals were maintained on their respective diets. Rats, 9–10 weeks old, were trained in the maze with three open channels. Two weeks later they were tested in the maze with six open channels. Three trials per rat per day were executed on four consecutive days. A rest period of at least 20 min was allowed between trials. The animals were dried with a towel after each swim. Errors were counted during trials 4–12 and consisted of the number of times the rat missed an opening, entered a blind alley, or backtracked. To prevent overfatigue, animals that failed to reach the ramp within 3 min were assisted through the openings and the errors cumulated during this period were recorded. Animals that failed to master the three-channel maze in 10–12 trials during the training period were eliminated from the experiment as inherently poor learners.

Data were analysed statistically by the method of variance<sup>7</sup>. There was no significant difference between replicated experiments conducted with different lots of animals.

Table 3. ANALYSIS OF WATER MAZE TEST

Group	No. rats	Average body weight (g)	Mean errors ± standard error			Mean swimming times ± standard error Trials 10, 11, 12 (sec/trial)
			Trials 4, 5, 6	Trials 7, 8, 9	Trials 10, 11, 12	
1	10	275	8.9 ± 1.2	3.6 ± 1.0	2.1 ± 0.8	14.9 ± 1.9
4	9	265	15.2 ± 3.9	8.1 ± 1.8	3.0 ± 1.0	12.7 ± 1.1
5	10	193	14.8 ± 2.8	7.9 ± 2.2	4.3 ± 0.8	12.0 ± 0.7
6	9	199	13.1 ± 2.6	3.3 ± 1.1	2.0 ± 0.6	13.6 ± 0.4
7	14	189	24.5 ± 4.0	10.7 ± 1.6	4.2 ± 0.7	14.4 ± 1.1

There is no significant difference between any two groups of animals in either the number of errors made or in the time required to swim through the maze of six channels during trials 10–12. The differences observed in the rate of maze learning, as measured by the number of errors made during trials 7–9, is attributed to imposed dietary regimens.

Table 5. EFFECT OF L-PHENYLALANINE ON RECOVERY FROM VITAMIN B<sub>6</sub> DEFICIENCY

Group	Diet Py (mcg/g) PAS (mg/g)	No. rats	Learning test		Growth		Acrodynia, loss of fur		
			Mean errors ± standard error	P (groups compared)	Mean weight gain ± standard error g/day/rat	P (groups compared)	Recovered	No change (No. of rats)	More severe
8	100	13	3.3 ± 0.6	0.05–0.01 (8, 9)	4.6 ± 0.3	0.001 (8, 9)	13	0	0
9	100	20	6.8 ± 1.0	0.2 (9, 11)	1.9 ± 0.3		1	17	2
10	70	14	3.8 ± 0.8	0.05 (10, 11)	2.7 ± 0.2	0.001 (10, 11)	4	17	0
11	0	20	8.6 ± 1.6		1.2 ± 0.2		1	17	2

Py = pyridoxine HCl, PAS = L-phenylalanine supplement.

Fig. 2. Learning curves. Animals behaved very erratically during the first 5–6 trials. The total number of errors made during trials 7–9 served as a criterion of learning. ●—●, Group 1 (10♂) control diet; ○---○, group 2 (9♂) control + L-phenylalanine.

It is apparent from the results, summarized in Tables 4 and 5, that diets containing large amounts of phenylalanine and pyridoxine inhibit learning in rats. The data further suggested that deficient mental performance is caused not by lack of pyridoxine but rather by interference of pyridoxine metabolism.

A sub-optimal intake of pyridoxine (group 5) did not produce any decided effect on maze learning; neither did a supplement of phenylalanine added to a pyridoxine free diet (group 6). In contrast, a diet high in phenylalanine as well as pyridoxine (groups 3 and 4) not only caused a marked reduction in maze learning but also produced retarded growth, loss of fur and loss of balance.

Table 4. EFFECT OF DEOXYPYRIDOXINE AND OF L-PHENYLALANINE SUPPLEMENT ± PYRIDOXINE ON MAZE LEARNING

Group	No. rats	Composition of diet			Mean errors ± standard errors	Groups compared	P
		Py mcg/g	PAS mg/g	Weeks fed

		0	70	2			
7	17	0	0	3	10.7 ± 1.6	7 and 5	0.05
		+DOP				7 and 1	<0.001
						7 and 2	<0.001

All of the diets contained 32 per cent potato starch, 28 per cent sucrose, 5 per cent corn oil, 20 per cent vitamin-free casein (Borden), 4.4 per cent salt mixture (Hegsted), 9 per cent cellulose and adequate amounts of all of the vitamins<sup>15</sup> with the exception of pyridoxine, the amount of which was varied. The content of cellulose was correspondingly decreased in the diets that were supplemented with L-phenylalanine. Py = pyridoxine hydrochloride, PAS = L-phenylalanine supplement, DOP = deoxypyridoxine.

A few animals of groups 4 and 7 could not maintain balance in the water maze; these were eliminated from the experiment. Loss of fur was observed in a few animals of Group 4.

These effects were also observed in animals treated with the B<sub>6</sub> inhibitor deoxypyridoxine (group 7).

Retarded learning, poor growth, acrodynia and loss of fur were observed in animals fed deoxypyridoxine. Addition of pyridoxine to the diet (group 8) brought about full recovery in all the animals. When pyridoxine, however, was fed with phenylalanine (group 9) these B<sub>6</sub> deficiency symptoms<sup>8,9</sup> persisted in 95 per cent of the animals and became more severe in a few. Apparently the utilization of pyridoxine for recovery was prevented.

The experimental evidence suggests that in phenylketonuria vitamin B<sub>6</sub> function is impaired by an inhibitory substance formed from dietary phenylalanine and pyridoxine. The enzyme for the decarboxylation of phenylalanine to phenylethylamine<sup>10</sup> is present in brain tissue. Pyridoxal is found in normal brain<sup>11</sup>. Thus the reaction of phenylethylamine with pyridoxal to yield the Schiff base pyridoxylidene phenylethylamine may readily take place in the brain. This Schiff base has been detected in phenylketonuric urine but not in normal urine. Phenylketonuric patients are known to form abnormally large amounts of phenylethylamine<sup>12</sup>. Among the known products of phenylalanine metabolism formed in excessive amounts by phenylketonurics, phenylethylamine has the most potent effect on the central nervous system. This supports the suggestion that pyridoxylidene phenylethylamine may interfere with vitamin B<sub>6</sub> function and thus cause the mental derangement associated with phenylketonuria.

We thank J. Ellis and R. Kennedy for technical assistance, and T. Ritman for criticism of the manuscript.

### Phenylketonuria in Rats: a Model for Biochemical Studies

Polidora, Cunningham and Waisman<sup>1</sup> reported that induced phenylketonuria (PKU) in rats does not adequately simulate the irreversible intellectual impairments found in the phenylketonuric child, although they point out that there is somewhat general agreement in the literature that this technique provides an adequate model of PKU for biochemical studies. The results of our experiments on the metabolism of phenylalanine in normal and PKU rats suggest, however, that even from the biochemical point of view there is no adequate simulation of impairments in the phenylketonuric child.

Weanling male rats of the Wistar strain were made phenylketonuric by feeding a normal protein test diet containing 5 per cent L-phenylalanine for 1 week. This was followed by a diet containing 7 per cent L-phenylalanine<sup>2</sup>.

Our contention that these PKU rats do not provide an adequate biochemical model for the study of PKU is based on the following facts: (1) All the rats had very high concentrations of free tyrosine in the plasma. In most cases, soon after the initiation of the high phenylalanine diet the concentration of tyrosine in the plasma was much higher than that of phenylalanine. One week later all the rats had higher free tyrosine concentrations. (2) The rats all gave positive results when tested with ferric chloride and dinitrophenylhydrazine early in the experiment. These tests are indicative of high phenylpyruvic acid excretion. On the other hand, when the rats were maintained on the special diet for 3-4 weeks they no longer gave these positive tests although the plasma concentrations of phenylalanine and tyrosine were still high. Instead of the blue-green colour indicative of a positive ferric chloride test, a dark brown spot was obtained. The dinitrophenylhydrazine test showed small traces of a yellow precipitate but only after the mixture had stood for several hours at room temperature. (3) When the rats were taken off the high phenylalanine diet for only a few hours there were drastic changes in the plasma levels of phenylalanine and tyrosine. There were also alterations in the concentrations of other amino-acids in the plasma. After 2 weeks on the diet rich in phenylalanine, one rat had 0.90 mmoles phenylalanine/ml. and 1.50 mmoles tyrosine/ml. in the plasma. Fasting for 24 h lowered these values to 0.033 and 0.067 mmoles/ml. The rat was then fed the diet rich in phenylalanine for 5 days and the phenylalanine and tyrosine plasma concentrations were then 0.35 and 0.94 mmoles/ml. A 6-h fast lowered these values to 0.090 and 0.490 mmoles/ml.

Because of these changes in the amino-acid levels it was impossible to obtain reproducible results in the study of the metabolism of D,L-phenylalanine-3-<sup>14</sup>C unless the high phenylalanine diet was kept in the metabolic cage during the 24-h experimental period.

(4) In human phenylketonurics only 10 per cent of the ingested phenylalanine is converted to tyrosine while 85 per cent is excreted in the urine as phenylalanine, O-hydroxyphenylacetic acid, phenylpyruvic acid, phenyllactic acid and phenylacetic acid<sup>3,4</sup>. Our results show that 24 h after the injection of D,L-phenylalanine-3-<sup>14</sup>C, 26.0 per cent of the carbon-14 was found in the expired carbon dioxide, while only 7.4 per cent was excreted in the urine. The remaining carbon-14 was incorporated into tissue proteins.

(5) After the injection of radioactive phenylalanine, the proteins obtained from the plasma were hydrolysed and analysed. 2 h after injection 88 per cent of the carbon-14 incorporated into the protein could be accounted for by radioactive phenylalanine while 12 per cent was in the form of radioactive tyrosine. After 24 h these values were 80 and 20 per cent respectively. In normal rats 24 h after the same injection, 78 per cent of the radioactivity in the proteins was in the form of phenylalanine and 22 per cent in the form of tyrosine. In PKU patients Udenfriend and Bessman<sup>5</sup> have found that only about 1.5 per cent of the radioactivity of the plasma proteins comes from labelled tyrosine derived from injected radioactive phenylalanine.

(6) There is a considerable distortion of the pattern of distribution of the plasma amino-acids in phenylketonuria. Linneweh and Ehrlich<sup>6</sup> reported that plasma concentrations of lysine, threonine, serine, aspartic acid, alanine and tyrosine were significantly lower than normal. Another study<sup>6</sup>, reviewed in Table 1, showed that the concentrations of most of the plasma amino-acids of the PKU patient are lower than those of the normal individual. We have determined the free amino-acid concentration in the plasma of four rats which were maintained for 10 days on a diet rich in phenylalanine. The distribution of the amino-acids in the plasma of PKU rats is quite different from that in PKU patients (Table 1). There is a greater variation from normal in the amino-acid concentrations in the PKU rats; the levels of glutamic acid, glycine and

arginine are lower, while those of certain sulphur and basic amino-acids, as well as the aromatic amino-acids, were greatly increased. The values for isoleucine and leucine varied little, while glutamine is not present at all, although it is found in the plasma of normal rats.

It appears that the modification of amino-acid and protein metabolism in PKU rats is different from that found in human beings with PKU.

Table 1. PERCENTAGE VARIATION OF PLASMA AMINO-ACIDS IN PKU AND NORMAL HUMANS (A) AND PKU AND NORMAL RATS (B)

	A PKU patient (ref. 7) (per cent)	B PKU rats (per cent)
thr	-14.6	-28.2
ser	-6.6	-27.6
glu	-48.0	-71.6
pro	-41.0	-56.9
gly	-10.5	-72.1
ala	-20.0	-26.9
val	-38.4	-25.6

his	-31.5	+8.3
arg	-51.8	-77.7
phe	+180.0	+590.0
asp	—	-64.3

These findings indicate that induced PKU is a very temporary state in which the high plasma phenylalanine concentration can change rapidly with variations in the diet. The very high plasma tyrosine concentration suggests that the rats are in a state of tyrosyluria<sup>7</sup> rather than phenylketonuria. Further, most of the injected radioactive phenylalanine is still metabolized by way of the normal tyrosine pathway. All these observations differ from those reported in human beings with PKU.

### Effects of Steroids on Chrysanthemum in relation to Growth and Flowering

THE physiology of flower initiation has been much investigated for more than half a century. It is now established that in conditions of inductive day length the leaves produce a hormone which induces differentiation in the apical meristem. The chemical nature of the hormone has not yet been definitely established. There have been many investigations of the effect of different organic compounds on plants in relation to flowering. The primary motive has been to look for compounds that could possess "florigenic" activity. Some workers have used various antimetabolites in an attempt to determine whether any of them block the synthesis of the floral stimulus, which could provide some indirect indications as to the nature of the hormone. Antimetabolite investigation has suggested that the flowering hormone may be a steroid or an isoprenoid-like compound<sup>1</sup>. Work on a strawberry variety has shown that unsaponifiable lipid fractions from flowering plants promote flowering in

the vegetative ones<sup>2</sup>. The active substance may include vitamin E and certain unidentified sterols. This communication reports the effects of steroids on flowering of chrysanthemum plants in non-inductive conditions.

Eleven common steroids of both plant and animal origin were selected at random (ranging from C<sub>19</sub> to C<sub>30</sub>). These were as follows: cholesterol (C<sub>27</sub>);  $\beta$ -sitosterol (C<sub>29</sub>); cholesteryl acetate (C<sub>29</sub>); lanosterol (C<sub>30</sub>);  $\Delta$ -5-3-acetoxy-bisnorcholeonic acid (C<sub>24</sub>); digitalin (C<sub>23</sub>); glycocholic acid (C<sub>26</sub>); androsterone (C<sub>19</sub>); androstane (C<sub>19</sub>); 21-acetoxypregnenolone acetate (C<sub>25</sub>); stigmasterol.

Concentrations of 100 and 500 p.p.m. of each steroid were applied as sprays to chrysanthemum plants. The steroids were dissolved in 5 ml. of peanut oil, mixed with water along with 5 ml. of 'Plyac', an emulsifying and surface active agent, and made up to volume with water.

Rooted cuttings of chrysanthemum, variety 'Princess Anne', were obtained from Yoder Brothers, Ohio. On receipt, the cuttings were planted in 4 in. earthen pots. Garden soil rich in organic matter was used as the growth medium. Two days after transplanting, the plants were transferred to a greenhouse bench and were exposed to a 22 h photoperiod. Hundred watt bulbs were spaced 4 ft. apart and 3 ft. above the plant surface, and provided a minimum light intensity of 150 ft.-candles<sup>3</sup>. The lights were automatically turned on at 6 p.m. every day and were turned off at 3 a.m. the following day. The greenhouse was kept moderately warm with a steam-heat unit. Plants were watered daily with tap water and once a week 50 ml. of a complete nutrient solution was applied to each plant. Plant heights were recorded once every month.

A randomized block design with two replications of five plants each was employed. Plants were selected for their uniformity and vigour. On November 9, 1964, when the average height of the plants was approximately 9 in., they were treated with the steroid solutions. Applications were made with hand spray guns, and the leaves were drenched with the solution. A second application of the steroid sprays was made after 1 week.

Fourteen weeks after the initial treatment, the plant tips were collected, and immediately immersed in a killing and fixing solution ('Craft III'). Slides were prepared from the shoot apex, then stained with safranin and fast green before floral initiation was evaluated<sup>4,5</sup>. Evaluations were made by comparing them with the slides made from chrysanthemum buds, collected at different stages of initiation. The results are presented in Table 1.

The results of steroid sprays in stem elongation are illustrated in Table 1. The differences between certain treatments may have appeared to be significant, but when analysed statistically the observation did not hold true, because of the wide variability present in the individuals within a treatment. The two concentrations of the steroids used also did not show any marked difference as far as stem elongation was concerned.

The effects of steroids on intact plants or on the growth of isolated plant parts have been investigated by many

Table 1. EFFECTS OF STEROID SPRAYS AT TWO CONCENTRATIONS ON STEM ELONGATION AND FLOWER BUD INITIATION IN CHRYSANTHEMUM PLANTS

Treatments	Plant heights in in.		Per cent of plants initiated <sup>a</sup>	
	100 p.p.m.	500 p.p.m.	100 p.p.m.	500 p.p.m.
Cholesterol	22.18	21.45	10	10
$\beta$ -Sitosterol	22.05	22.70	50	10
Cholesteryl acetate	23.80	23.15	20	None

Androsterone	21.75	22.10	10	None
Androstane	22.20	23.70	10	10
21-Acetoxypregnenolone	22.75	22.15	30	None
Control	23.05	22.08	20	10

Results are average of ten test plants.

Heights were measured 6 weeks after the initial treatment.

Terminal buds were collected 14 weeks after the initial treatment and then dissected to evaluate floral response.

workers. Their work suggests that oestrone and saponins are active in the promotion of plant growth; and all other steroids of either plant or animal origin tested so far have been found to be either ineffective or slightly inhibitory in their action<sup>6</sup>. Results of this investigation are in agreement with previous findings.

From the data in Table 1 in relation to flower bud initiation, it can be seen that two steroids,  $\beta$ -sitosterol and lanosterol, at a concentration of 100 p.p.m., have resulted in flower initiation in 50 per cent and 40 per cent plants respectively. Only 10 per cent of plants were found to be initiated in each of the following treatments: cholesterol, stigmaterol, digitalin,  $\Delta$ -5-3-acetoxybisnorcholenic acid, androstosterone, and androstane. With the exception of glycocholic acid and 21-acetoxypregnenolone acetate, 30 per cent of plants were initiated; 20 per cent of plants were found to be initiated in the other two treatments, including the control.

When plants were treated with 500 p.p.m. of glycocholic acid, 50 per cent of plants set flower buds. Four other steroids at this concentration were effective, while lanosterol and stigmaterol have initiated buds in 20 per cent of the treated plants. Ten per cent of plants were found to have initiated flower buds in all other treatments, including the control.

Induction of flowering with sterols has not been reported before. Only Chouard<sup>7</sup> has demonstrated that application of oestradiol in short day conditions greatly enhances the onset of flowering in *Callistephus sinensis*. The present finding that  $\beta$ -sitosterol, lanosterol and glycocholic acid may in some way promote floral initiation needs to be investigated in some detail.

We thank Yoder Brothers, Ohio, for the supply of chrysanthemum cuttings.

This investigation was supported by a grant from the U.S. National Science Foundation.

### Inhibitory Effect of Salicylates and Cinchophen Derivatives on Amino-acid Incorporation

CINCHOPHEN is an ulcerogenic drug which depresses gastroduodenal mucus formation<sup>1</sup>. Salicylic acid also causes alimentary bleeding. It is possible that failure to secrete mucus for protection against peptic digestion of the gastroduodenal wall, in addition to chemical changes in the wall structure, is the ultimate cause of bleeding. We have therefore undertaken to investigate the effects of cinchophen, salicylic acid and their derivatives on protein synthesis.

There are discrepancies in published reports on the effect of salicylate on the cell-free incorporation of amino-acid into protein. According to Weiss *et al.*<sup>2</sup> salicylic acid stimulates the incorporation of labelled leucine into protein, whereas Dawkins *et al.*<sup>3</sup> reported an inhibitory effect.

Female rats aged 4-5 months fed *ad libitum* were killed by a blow on the head, bled and the liver excised and

homogenized immediately in three volumes of ice cold 0.25 molar sucrose buffered to pH 7.4 with 50 mmolar *tris* hydrochloric acid buffer containing 10 mmolar magnesium chloride and 50 mmolar potassium chloride. The homogenate was centrifuged at 15,000g for 10 min, and the precipitate discarded. The supernatant was used as such or treated either to isolate the ribosomes or to prepare the pH 5 fraction. The ribosomes were isolated as follows: 0.5 per cent of deoxycholate was added to a sample of supernatant which was stirred carefully for 2 min. It was then centrifuged at 130,000g for 1 h through layers of 15 and 20 per cent sucrose containing magnesium and potassium chlorides as the homogenizing mixture. This produced a precipitate of the ribosome preparation. The fraction at pH 5 was prepared as follows: the pH of another sample of the 15,000g supernatant was adjusted to 5.2 with an acetic acid-potassium acetate buffer, pH 5.0. The sample was centrifuged at 3,000g for 15 min and the precipitate washed and dissolved in sucrose-*tris* solution as before and used as the pH 5 fraction. All operations were carried out in either an ice bath, a cold room or a refrigerated centrifuge. In experiments with synthetic messengers (Tables 2 and 3) the mixture was preincubated for 15 min before the addition of polyuridylic acid on polyadenylic acid, amino-acid and inhibitor. In all experiments the final incorporation mixture was incubated in a water bath at 37° C for 30 min. The reaction was stopped by the addition of 1 ml. of 10 per cent TCA, the precipitate separated by centrifugation at 1,500g for 10 min, washed twice with 2 ml. of 5 per cent TCA, twice with ethanol containing 10 per cent sodium acetate and once with ethanol-ether 1:1. The washed precipitate was dissolved in 0.2 ml. of 1 molar hyamine hydroxide in methanol and its radioactivity determined in a liquid scintillation counter after mixing with 4 ml. of toluene-based POP-POPOP liquid scintillation mixture. The results were corrected for quenching by internal standardization. The inhibition was calculated as the percentage decrease of the standards without an inhibitor.

The strongest inhibition is shown by salicylaldehyde, decreasing somewhat in the case of salicylic acid, cinchophen and its 3-hydroxy derivative, and decreasing still more in the case of acetylsalicylic acid; whereas salicylamide and the other hydroxy derivatives of cin-

Table 1. INHIBITION OF LEUCINE INCORPORATION INTO THE 15,000g SUPERNATANT FRACTION OF RAT LIVER. THE RESULTS ARE EXPRESSED AS PER CENT DECREASE OF INCORPORATION COMPARED WITH UPTAKE IN AN INHIBITOR-FREE SYSTEM

Inhibitor concentration:	10 <sup>-3</sup> molar	
Cinchophen	20%	33%
3-Hydroxy cinchophen	37	36
6- " "	4	16
7- " "	4	6
8- " "	2	0
Salicylic acid	34	36
Acetylsalicylic acid	19	22
Salicylamide	0	5
Salicylaldehyde	71	65

Incubation mixture contained: 50 mmolar *tris*-hydrochloric acid buffer pH 7.4, 1 mmolar ATP, 10 mmolar creatine phosphate, 0.4 mmolar GTP, 50 mmolar potassium chloride, 10 mmolar magnesium chloride, 10 mmolar GSH, 0.2 ml. 15,000g supernatant of liver homogenate 1:3, 250 m $\mu$ C-leucine, 100  $\mu$ g other amino-acids and inhibitor in a total volume of 1 ml. Columns represent two independent experiments.

Table 2. PER CENT INHIBITION OF POLYURIDINE DIRECTED PHENYLALANINE INCORPORATION

Inhibitor concentration:	10 <sup>-3</sup> M	3 $\times$ 10 <sup>-3</sup>	
	per cent inhibition	per cent inhibition	
Cinchophen	37	41	55
3-Hydroxy cinchophen	45	42	52
6- " "	10	10	
7- " "	1	0	
8- " "	-2	6	
Salicylic acid	39	35	62
Acetylsalicylic acid	23	23	43
Salicylamide	0	2	28
Salicylaldehyde	71	77	96
Salicylic acid + DNA (5 mg)	47	37	
Salicylic acid + albumin (5 mg)	10	15	

The incubation mixture was the same as in Table 1 except that instead of the homogenate supernatant it contained pH 5 fraction (0.3 mg protein), ribosomes (1.4 mg protein) and polyuridylic acid 100  $\mu$ g. The only amino-acid added was phenylalanine labelled with carbon-14, 250 m $\mu$ C.

cinchophen investigated had almost no effect. The addition of extra protein to the incorporation mixture resulted in protection against inhibition (Table 2), whereas addition of DNA was without effect. Equilibrium dialysis showed that these drugs were bound to albumin but not to DNA or RNA. Thus the decreased inhibition indicated in Table 1 when compared with Tables 2 and 3 can be assumed to be the result of a lower free drug concentration caused by a higher protein concentration.

Our earlier experiments have shown that hydroxylation of cinchophen does not abolish its inhibitory action on aspartate: 2-oxoglutarate and alanine: 2-oxoglutarate transaminases<sup>4</sup> and uridine diphosphate glucose dehydrogenase *in vitro*. On the other hand, the hydroxy derivatives of cinchophen with the exception of 3-hydroxy cinchophen are not ulcerogenic in dogs *in vivo*, and this may be explained by their failure to inhibit protein synthesis.

Table 3. PER CENT INHIBITION OF POLYADENINE DIRECTED LYSINE INCORPORATION

Inhibitor concentration:	10 <sup>-3</sup> M		3 × 10 <sup>-3</sup> M	
	per cent inhibition		per cent inhibition	
Cinchophen	32	35	55	44
3-Hydroxy cinchophen	42	33	50	53
6- " "	12	11		
7- " "	7	8		
8- " "	16	4		
Salicylic acid	44	32	61	60
Acetylsalicylic acid	17	26	40	43
Salicylamide	5	2	25	20
Salicylaldehyde	70	71	98	97

Incubation mixture was the same as in Table 2 except that polyuridylic acid was substituted by polyadenylic acid and phenylalanine by lysine labelled with carbon-14, 250 mμ.

The results obtained are in good agreement with those reported by Dawkins *et al.*<sup>3</sup> in investigations of salicylic acid action.

A brief report of this investigation was presented earlier<sup>5</sup>.

### Photochemical Degradation of Diquat

DIQUAT as the dibromide (I) is the active constituent of 'Reglone'\* herbicide, which is being used in a wide variety of weed control problems<sup>1</sup>. It has been shown<sup>2,3</sup> that the related bipyridylum herbicide 'Gramoxone\*', based on the paraquat cation, is subject to significant photochemical degradation in sunlight at certain times of the year; the present communication is concerned with the breakdown of diquat dibromide when exposed to sunlight, which has been studied in the course of a detailed examination of the fate of the chemical after application.

'Reglone' is used to control water weeds at concentrations of about 1 p.p.m. of ion in the water. Consequently,

\* Registered trade mark of Plant Protection, Ltd.

Fig. 1. Degradation of dilute aqueous <sup>14</sup>C-bridge-labelled diquat dibromide in sunlight. (Autoradiograph of paper chromatogram.)

the first experiments on the photochemical degradation of diquat were undertaken using very dilute solutions of the chemical. A solution of 0.4 mg of <sup>14</sup>C-ethylene bridge-labelled diquat dibromide in 100 ml. of water contained in a crystallizing dish covered by a sheet of polythene 0.1 mm thick was exposed to sunlight during the summer for several weeks. (There is very little radiation in sunlight with a wavelength below 300 mμ and none below 290 mμ (ref. 4); it has been shown that polythene sheet 0.1 mm thick does not absorb any radiation above 290 mμ.) 0.5-Ml. portions of the irradiated solution were removed at intervals, concentrated and applied to the origin of a strip of Whatman No. 1 chromatography paper. The chromatogram was developed using a mixture of *n*-butanol, acetic acid and water (4 : 1 : 2) and placed in contact with X-ray film. The resulting autoradiograph showed that one principal radioactive decomposition product was formed (compound A in Fig. 1). Diquat, when present on the chromatogram, was revealed by means of potassium iodoplatinate solution<sup>6</sup>; the decomposition product quenched the induced fluorescence of the paper when the chromatogram was observed under ultra-violet light.

In order to study the photochemical degradation more conveniently, trial experiments were carried out by stirring 10–20 ml. of <sup>14</sup>C-diquat dibromide in 0.1 per cent (w/v) aqueous solution in a beaker and exposing them to ultra-violet light. When a 'Hanovia' Model 16 lamp, without a filter, was used as the light source, very rapid and complete degradation of the diquat occurred. Using either <sup>14</sup>C-ethylene bridge or <sup>14</sup>C-ring-labelled material, almost no radioactivity remained in solution within 24 h of the start of irradiation; apparently the diquat was degraded to volatile fragments. When the light from this lamp was filtered through a sheet of borosilicate glass 2 mm thick, however, it caused the same type of degradation of the chemical as occurred in sunlight. (Borosilicate glass effectively absorbs all radiation below about 300 mμ.) Compound A was the chief radioactive degradation product whether <sup>14</sup>C-bridge or <sup>14</sup>C-ring-labelled diquat was irradiated.

The reaction was then conducted on a larger scale using a 'Hanovia 10L' photochemical reactor with a borosilicate glass down-tube which contained a mercury vapour arc tube at medium pressure. Oxygen was passed at a rate of approximately 2 ml./sec through an irradiated solution of 15 mg <sup>14</sup>C-ring-labelled diquat dibromide in 1 l. of water, and 10-ml. portions were removed at intervals and their ultra-violet spectra examined. As the reaction proceeded, the light absorption of diquat (λ<sub>max</sub> = 310 mμ) decreased, and a new absorption band at 270 mμ appeared, due to the formation of compound A. The samples were evaporated to small bulk and applied to a paper chromatogram which showed on development that the degradation of diquat was similar to that which occurred in sunlight. The reaction was repeated using 10 l. of solution containing 200 mg of diquat dibromide to enable enough of the degradation product to be obtained to allow it to be

identified: this larger scale reaction took 14 days to complete. The resulting solution was percolated through a column of 'Dowex 50W-X8' cation-exchange resin in the hydrogen form, elution being effected with increasing specified strengths of aqueous formic acid and followed by measuring the ultra-violet absorption of the eluate at 270 m $\mu$ . Compound A was eluted with 40 per cent formic acid and removal of the solvent gave a yellow amorphous solid. Paper chromatography of this solid showed that several minor components were present, but compound A predominated. The crude solid was converted to the hydrochloride by treatment with saturated methanolic hydrogen chloride, and after removal of the excess reagent the material was recrystallized from methanol and ethyl acetate to give the chromatographically pure compound as a white amorphous solid whose melting point was greater than 300°C.

Compound A was radioactive whether it was prepared from  $^{14}\text{C}$ -ring-labelled or  $^{14}\text{C}$ -bridge-labelled diquat and therefore contained at least one intact ring and at least one of the bridge carbon atoms. The reaction with potassium iodoplatinate to give a black precipitate indicated the presence of a quaternary nitrogen atom. Elemental analysis, together with infra-red, ultra-violet, nuclear magnetic resonance, and mass spectral data of the compound, were consistent with the tetrahydro-oxo-pyridopyrazinium structure (II,  $X = \text{Cl}$ ).

The nuclear magnetic resonance spectrum showed a complex multiplet between 0.8 and 1.8  $\tau$  assignable to the signals from the four aromatic protons. Two triplets at 4.92 and 5.96  $\tau$  ( $J = 7$  c/s in both instances) are attributed to the  $\geq \text{N}-\text{CH}_2-$  and the  $-\text{CH}_2-\text{NH}-$  proton resonances respectively, this type of splitting being typical of an  $A_2B_2$  proton system. The mass spectrum of the pure solid supported the structural assignment. A peak at  $m/e$  149 corresponds to the mass number of the ion derived from II ( $\text{C}_8\text{H}_8\text{N}_2\text{O}$ ), while a peak observed at  $m/e$  120 suggests loss of a  $-\text{CH}_2-\text{NH}-$  fragment. Further peaks at  $m/e$  106 and  $m/e$  78 can be attributed to the ions (III) and (IV) respectively.

The structure was finally confirmed by synthesis. The condensation product (V;  $X = \text{OH}$ ) prepared by heating ethyl picolinate with ethanolamine was treated with thionyl chloride to give the chlorethylamine hydrochloride (VI). The free base (V;  $X = \text{Cl}$ ) obtained by exact neutralization of the amide hydrochloride (VI) with aqueous sodium hydroxide was heated, in the absence of solvent, when ring closure took place smoothly to give 1,2,3,4-tetrahydro-1-oxo-pyrido [1,2,  $\alpha$ ]-5-pyrazinium chloride (II;  $X = \text{Cl}$ ) in excellent yield.

The synthetic compound and compound A had superimposable infra-red spectra, and their chromatographic properties were identical.

Compound II is interesting in that it has a unique ring structure and its formation from diquat presumably involves an intermediate such as (VII) which then undergoes oxidation.

Compound II is also formed when diquat adsorbed on filter paper and silica gel is exposed to sunlight. There is an interesting contrast between the photochemical behaviour of diquat and paraquat. The latter, with maximum ultra-violet light absorption at 257 m $\mu$ , is not degraded in solution by sunlight. When it is adsorbed on a surface, the maximum light absorption moves to a higher wavelength (Talbot, P. J., personal communication) so that sufficient radiation from sunlight above 290 m $\mu$  is absorbed to lead to some degradation of paraquat. Diquat, with its light absorption maximum at 310 m $\mu$ , is able to absorb sufficient radiation from sunlight to be degraded even in solution.

In addition, diquat is degraded photochemically after it has been applied to plants (metabolic degradation of the chemical in plants does not occur<sup>1</sup>). Unlike the photochemical degradation of paraquat on plants, that of diquat is very extensive, and very little of the latter remains on plants after exposure to sunlight for a week or so in summer. Compound II seems to be formed, but it is unlikely that this material, or any others formed in the photochemical degradation, will be translocated into harvested parts of the plants, because the degradation takes place on plants largely after they are dead. (It has been shown<sup>2</sup> that no translocation of the photochemical degradation products of paraquat occurs from dead leaves.) Furthermore, compound II ( $X = \text{Cl}$ ) has a very low oral toxicity to mammals. Details of the work on the degradation of diquat on plants will be published elsewhere: work is continuing on the structural elucidation of the minor photochemical breakdown products.

We thank Dr. G. R. Bedford and Dr. B. Webster, of I.C.I. Pharmaceuticals Division, who measured the nuclear magnetic resonance spectrum and the mass spectra and assisted in the interpretation.

### Reversibility of a Penicillamine Induced Defect in Collagen Aggregation

WE have recently reported that the administration of penicillamine ( $\beta,\beta$ -dimethylcysteine) results in a marked accumulation of soluble collagen in the skin of rats<sup>1</sup>. Ultra-centrifugal analysis of this thermally denatured material indicated that it consists almost exclusively of strands of  $\alpha$ -collagen<sup>2</sup>. The pattern obtained appeared to be identical to that observed after the administration of lathyrogenic compounds such as  $\beta$ -aminopropionitrile<sup>3</sup>. In addition to the changes in solubility, animals treated with penicillamine also manifested a decrease in the tensile strength in the intact skin and in healing wounds<sup>1</sup>.

These observations prompted us to investigate the relationship between the duration of penicillamine administration to skin changes in: *a*, soluble collagen; *b*, insoluble collagen; and *c*, tensile strength, as well as in the rate and degree of reversibility of these changes on withdrawal of the drug.

DL-Penicillamine was fed to young male rats (60–70 g) of the Holtzman strain. The drug was incorporated into the diet at 0.25 per cent concentration. The dose was calculated on the average of food intake of the rats and is stated in Figs. 1 and 2. Pyridoxine was also added to the diet at a concentration of 100 mg/kg of diet, inasmuch as Wilson and du Vigneaud found that DL-penicillamine produced a pyridoxine deficiency, presumably by the formation of a thiazolidine complex<sup>4</sup>. This degree of supplementation has been shown to overcome the inhibitory effects of DL-penicillamine on growth. D-Penicillamine was used in recent experiments in which it showed the same properties as the DL isomer. The D form is more satisfactory because of its decreased toxicity and lesser interaction with pyridoxine. Initial values were obtained by killing eight rats at the start of the experiment. The animals were then placed on penicillamine and groups of four or five rats were killed after 2, 3, 5, 6, 10 and 14 days. At this time the remaining animals were kept on the same basal diet with penicillamine removed. Skin specimens were analysed for collagen content and its solubility properties as previously described<sup>5</sup>. Only those fractions soluble in 0.5 molar sodium chloride and insoluble are reported in this communication, as they reflect the most significant and pertinent changes. In addition, a strip of skin (5 mm  $\times$  50 mm) cut from the dorsal area of the animal and parallel to the longitudinal axis was cut and used to measure the tensile strength in an 'Instron' machine. The force in grams required to rupture the skin is used as an index of tensile strength. The changes in the concentration of the 0.5 molar sodium chloride collagen fraction and insoluble collagen of skin during and after administration of penicillamine are shown in Fig. 1. After the first day of treatment a significant accumulation of soluble collagen occurred without

Fig. 1. Changes in collagen soluble in 0.5 molar sodium chloride and insoluble collagen of young rats treated with DL-penicillamine during 14 days and their reversal on discontinuing treatment.

any appreciable change in the amount of insoluble material present. After the first day, however, the amount of 0.5 molar sodium chloride collagen increased rapidly while the amount of insoluble material began to fall rather precipitously. Fig. 1 also demonstrates the rapid reversibility of the changes induced by penicillamine after withdrawal of the drug. The concentration of soluble collagen dropped quite rapidly with a concomitant rise in the insoluble collagen indicating that the process of aggregation was being re-established. There is a clear correlation between insoluble collagen concentration and tensile strength (Fig. 2). This was found to be the case in relating variations of insoluble collagen with age and tensile strength of rabbit skin<sup>6</sup>. Nevertheless, the slopes of the curves are different, probably because the insoluble collagen material is not a homogeneous substance but is composed of materials of different degrees of aggregation and inertness. It is reasonable to suppose that penicillamine causes a depletion of the more recently synthesized and consequently less cross-linked collagen. Inasmuch as the tensile strength of skin is primarily a manifestation of a more inert and cross-linked fraction of collagen, this parameter would not be expected to change as rapidly as the total insoluble collagen which includes both old and newly synthesized fibres. A similar assumption can be made to explain the reversal of these changes which occur when treatment is discontinued. The rate of increase of chemically determined insoluble collagen is greater than the simultaneous gain in tensile strength. It is interesting to note that a very marked and rapid increase in tensile strength occurred at the end of the second week of recovery. These changes show an overall similarity to the pattern we have observed in investigations of the changes of tensile strength of collagen in normal rabbit skin during the early stages of ageing<sup>6</sup>.

Fig. 2. Comparison of the insoluble collagen present in skin with its tensile strength during and following penicillamine treatment.

Our findings indicate that penicillamine definitely inhibits the aggregation of the soluble tropocollagen molecules to form insoluble fibrous material. The depletion of insoluble collagen may be explained by its rapid turnover in animals of this age. Consequently, the collagen which is broken down in this process is not replaced because of the blockage of aggregation brought about by penicillamine. Preliminary evaluation of our results supports this assumption, but a more detailed and quantitative analysis based on rates of turnover, syntheses and changes in pool size is necessary in order to ascertain the mechanism involved.

This investigation was supported by a research grant from the National Institute of Dental Research, U.S. Public Health Service.

We thank Merck, Sharp and Dohme for their generous supply of D-penicillamine.

### Double-disc Electrophoresis of Proteins

GEL electrophoresis in discontinuous buffer systems<sup>1</sup> is a valuable method of examining dilute protein solutions. By selecting pH conditions it is possible to concentrate and then separate either cationic or anionic proteins, but only in separate analyses. Thus, the *tris*-glycine system can be used, in which the running pH is 9.5 and most proteins migrate as anions<sup>1</sup>. The usual cationic proteins will either not migrate or will move backwards as a large zone equal in size to the origin. Conversely, an acidic system, such as  $\beta$ -alanine-acetate, may be chosen in which cationic proteins migrate at pH 4.0 (ref. 2), but in this case the anionic proteins are lost to further analysis. Apart from the loss of time and research material necessitated by separate analyses, there is an unavoidable ambiguity about the direction of migration of a particular protein, because it is quite possible for the same protein to migrate as an anion at pH 9.5 and as a cation at pH 4.0. Clearly, a single system allowing the simultaneous separation of oppositely charged proteins would be desirable. To this end the method described couples two discontinuous buffer systems which provide concentrating and running conditions for both cationic and anionic proteins in the same sample.

The apparatus consisted of two separate gel tubes joined by a 3 cm section of clear plastic hose pierced with a small opening for the introduction of liquid sample. One gel tube contained a weak acid (taurine,  $pK_a$  8.7) and its potassium salt, while the other contained a weak base (imidazole,  $pK_a$  7.0) and its chloride. The sample was photo-polymerized within the plastic hose and completed the ionic connexion between the gel tubes. In principle, the doubly discontinuous system should behave in the manner described by Ornstein<sup>3</sup>. That is, there would be an initial stacking of ions in the order of fast inorganic ions followed by slower charged proteins followed by imidazole<sup>+</sup> or taurine<sup>-</sup>. The stacking of ions towards opposite ends of the sample gel would produce sharp zones of cationic and anionic protein. Finally, these would be over-run by imidazole<sup>+</sup> or taurine<sup>-</sup> when the ion stack reached the running gel and the proteins would begin to separate on the basis of size and charge.

The gel and buffer formulations were as follows. (a) Cation running gel buffer: 1.2 ml. 1 molar potassium hydroxide, 0.75 g taurine, 25  $\mu$ l. tetramethylethylenediamine, made up with water to 10 ml. This system had an original pH of 8.1 and a running pH of 7.5. (b) Anion running gel buffer: 1.2 ml. 1 normal hydrochloric acid, 0.50 g imidazole, 50  $\mu$ l. tetramethylethylenediamine, made up with water to 10 ml., giving an original pH of 7.7 and a running pH of 8.3.

Running gels were formed by mixing two volumes of one of these buffer systems with two volumes of a solution of 20 g acrylamide, 0.8 g *N,N'*-methylbisacrylamide, 7.5 mg potassium ferricyanide, and water to 100 ml. with four volumes of 0.14 per cent ammonium persulphate

Fig. 1. Double-disc electrophoresis apparatus. Top, side view in cross-section showing the sample before polymerization. Bottom, same view during electrophoretic stacking of the sample anions and cations (shaded lines).

Fig. 2. Bean leaf peroxidases separated by double-disc electrophoresis. The photograph is a composite to show the original running position of the gel tubes. Peroxidase zones, some of which photograph poorly, are marked by short, vertical lines.

in water. The mixture was pipetted rapidly into glass tubes 55 mm long and 8 mm in internal diameter to within 1/8 in. of the top and layered carefully with water. Polymerization occurred in about 10 min as indicated by the formation of a refractile zone below the initial layer.

The sample gel (c) contained 200  $\mu$ l. of water containing enough safranin O and bromphenol blue to produce visible zones during electrophoresis; it also contained 150  $\mu$ l. of 1 per cent tetramethylethylenediamine in water, 150  $\mu$ l. of a solution containing 4 mg of riboflavin in 100 ml. of water, 150  $\mu$ l. of a solution of 40 per cent acrylamide and 10 per cent *N,N'*-methylenebisacrylamide in water, and 1.75 ml. of the sample in 0.025 molar phosphate at pH 7.0.

The components were quickly mixed and injected into the sample chambers, care being taken not to entrain air bubbles. In the present instance, 1 ml. of the mixture provided sufficient sample for a single analysis which was usually run in duplicate. The running gel tubes were pushed into the sample chamber so as to exclude air and to force a drop of sample up through the chamber opening (Fig. 1). A piece of plastic film was slid over the drop to seal off air and the chambers were exposed to bright fluorescent light until polymerization produced an opalescent gel. Alternatively, the sample chamber was closed by sliding in one of the gel tubes so as to cover the opening.

The units were connected vertically between two electrode boxes which were then filled with the following solutions: negative electrode box, 0.038 molar taurine and 0.0038 molar potassium hydroxide; positive electrode box, 0.038 molar imidazole and 0.0038 molar hydrochloric acid.

A typical run required about 2 h at 100 V, at which time the cationic (safranin O) and anionic (bromphenol blue) marker dyes had migrated 4 to 5 cm into their respective tubes. The gels were removed by the usual rimming technique<sup>1</sup> and stained for enzyme activity or protein. The analysis of bean leaf protein revealed three anionic peroxidases and seven cationic peroxidases using guaiacol and hydrogen peroxide as chromogenic substrates (Fig. 2).

## IMMUNOLOGY

**Serological Differentiation of *Pythium aphanidermatum* from *Phytophthora parasitica* var. *nicotianae* and *Ph. parasitica***

THIS report describes the use of serological techniques to distinguish two morphologically similar pathogenic fungi in soil. *Pythium aphanidermatum* (Edson) Fitzp. causes damping-off in many plants, including the tobacco (*Nicotiana tabacum* L.) and tomato (*Lycopersicon esculentum* Mill.) plants<sup>1</sup>. Recently Dukes *et al.* reported that this fungus also causes dark brown to black stem cankers on tomato seedlings grown in fields in South Georgia<sup>2</sup>. *Phytophthora parasitica* (Dast.) var. *nicotianae* (B. de Haan) Tucker [= *Phytophthora nicotianae* var. *nicotianae*<sup>3</sup>] causes black shank of tobacco in this same area of South Georgia<sup>4</sup>, and has been reported to cause damping-off of tobacco seedlings, as well as a disease of eggplant, tomato and other plants<sup>5</sup>. It is difficult to differentiate quickly between these two indigenous soil-borne fungi in the vegetative state, whether in culture or in host tissues. To identify these pathogens in host tissue when reproductive structures are lacking, it is necessary to isolate and grow them in culture on media suitable for production of asexual bodies. Some isolates of both species may produce reproductive structures very slowly or not at all<sup>6,7</sup>. Proper identification of these species thus may require considerable time and effort, especially by workers not familiar with this group of fungi.

It was therefore decided to apply serological techniques towards developing a rapid method of distinguishing these species. In addition, it was decided to compare serological properties of *Ph. parasitica* [= *Ph. nicotianae* var. *parasitica*<sup>3</sup>] with those of *Ph. parasitica* var. *nicotianae*, because the only apparent difference between these two fungi is the ability of the latter to cause black shank of tobacco<sup>8</sup>. Recently Haasis reported that isolates of *Phytophthora* from several hosts other than tobacco caused a disease on a susceptible tobacco variety<sup>9</sup>. Whether these isolates caused typical black shank symptoms, however, is not known.

Previous serological work with pythiaceae fungi includes that of Burrell *et al.*<sup>10</sup>, who found that species-specific sera were efficient for the identification of *Ph. cactorum* (Leb. & Cohn) Schroet., *Ph. cinnamomi* Rands and *Ph. erythroseptica* Pethyb. Antiserum of *Ph. cactorum* cross-absorbed with *Ph. erythroseptica* did not react with antigens of several other fungi, including *Ph. parasitica* and three *Pythium* species.

To prepare the antisera, the three fungi were grown for 1 week at 28° C on a rotary shaker in potato glucose broth which consisted of the filtered juice from 200 g of fresh boiled potatoes, 20 g glucose, and distilled water to make up to 1,000 ml. Mycelia were then separated on a fine mesh nylon screen, washed twice with physiological saline, homogenized for 2 min in a blender and separated by centrifugation. They were resuspended in physiological saline, disintegrated in an ice bath for 10 min with a 'Branson S-75 Sonifier' at 6 amp, preserved with 1:10,000 'Thimersol', and kept at 4° C during the inoculation series. At first the preparations were injected intravenously into rabbits; however, 100 per cent mortality resulted with *Ph. parasitica* var. *nicotianae* inoculations. A modified injection schedule was therefore used as follows for each preparation: intramuscular injections of 1 ml. fungus suspension, plus 1 ml. 4 per cent sodium alginate adjuvant on the first and tenth day; intraperitoneal injections of 1, 2, 3, 4 and 5 ml. on the first, fourth, seventh, tenth and eighteenth days, respectively; and exsanguination on the twenty-eighth day. The antisera were frozen without preservatives.

Fungal materials for absorption studies were similarly prepared as used for the injection series except that no preservative was included. Antisera were absorbed by

mixing, intermittently, 2 ml. of absorbent with 2 ml. of antisera for 2 h at 37° C, and then clarifying antisera by centrifugation. Control antisera were treated similarly except that physiological saline was used instead of absorbent. Resulting preparations of antisera were tested in immuno agar diffusion plates against suspensions of disintegrated mycelia; reactant wells were 10 mm apart. Also, attempts were made to detect *Py. aphanidermatum* mycelium serologically in tomato stem lesions by homogenizing diseased tissue from several plants in physiological saline, filtering out coarse debris with a cheese cloth, concentrating the material by centrifugation, disintegrating the material by ultrasonification and testing the material against *Py. aphanidermatum* antiserum in immuno agar diffusion plates.

The results showed that *Py. aphanidermatum* antiserum was serologically specific; it was therefore unnecessary to absorb it. Undiluted *Ph. parasitica* var. *nicotianae* antiserum produced a faint band against *Py. aphanidermatum*, which was not evident after the antiserum was diluted 1:1 with physiological saline and incubated as an absorption control. The antiserum caused two sharp bands against each *Phytophthora* variety, but absorption with either variety removed all detectable antibodies. *Ph. parasitica* antiserum was serologically distinct from *Py. aphanidermatum* but was otherwise similar to *Ph. parasitica* var. *nicotianae* antiserum.

No precipitin lines formed when *Pythium*-infected tomato stems were tested against *Pythium* antiserum.

It is concluded that *Py. aphanidermatum* can be readily distinguished serologically from either *Ph. parasitica* var. *nicotianae* or *Ph. parasitica*, and that the two varieties of *Ph. parasitica* are serologically very similar. It was not possible to detect *Py. aphanidermatum* in infected tomato stems using immuno agar diffusion methods; however, suspected fungi could be isolated and then identified serologically. Also, the specificity of *Py. aphanidermatum* antiserum suggests that immunofluorescent techniques could effectively detect the species in mounts of infected tissue.

This research formed part of the co-operative investigations of the University of Georgia College of Agriculture Experiment Stations and the U.S. Department of Agriculture, Agricultural Research Service, Crop Research Division.

### Development of Immunological Memory during the Primary Immune Response

THE existence of immunological memory has been classically recognized by the appearance of a "secondary" type of antibody response to antigenic challenge of a previously immunized animal. Whereas the kinetics of the early phases of antibody production have been intensively investigated<sup>1</sup>, little is known about the development of immunological memory during the early stages of

the immune response. Lymphoid cells from animals previously stimulated with an antigen can respond to the same antigen in tissue culture with antibody production<sup>2</sup>, cellular proliferation<sup>3,4</sup> and increased synthesis of DNA<sup>5</sup>. Available evidence indicates that this *in vitro* response can be taken as evidence for the presence of specific immunological memory<sup>6</sup>. We have investigated the development of this capacity by measuring the incorporation of tritiated thymidine into the DNA of lymphoid cells from immunized rabbits on re-exposure to the antigen *in vitro*.

Albino rabbits were immunized with a single injection of 3-6 mg of keyhole limpet haemocyanin (KLH), either intravenously or in divided doses, into the hind foot pads. Cell suspensions of spleen and popliteal lymph nodes obtained at different intervals after immunization were cultured in minimum essential medium and 15 per cent pooled normal rabbit serum. Tritiated thymidine (<sup>3</sup>H-thymidine) was added after 24 h and cultures were terminated at the end of 3 days. Buffy coat cells of the peripheral blood, obtained after sedimentation in 6 per cent dextran (molecular weight 250,000), were cultured for 4 days, and tritiated thymidine was added on the second day of culture. Cultures without antigen and with varying amounts of KLH (0.0008-0.2 mg/ml.) were set up in triplicate. After culture, cells were collected, frozen and thawed, and extracted successively with 0.3 molar cold trichloroacetic acid, 44 per cent dimethylsulphoxide and twice with cold absolute ethanol. Samples were then dissolved in 0.1 normal sodium hydroxide and radioactivity was determined by liquid-gel scintillation. Absolute counts incorporated in cultures without antigen varied markedly from rabbit to rabbit, and so results have been expressed as the ratio of counts with antigen to counts without antigen. An increase of twofold or more was considered significant. Variation between duplicate cultures was usually less than 20 per cent.

Three days after intravenous administration of KLH, no detectable response was elicited in any of the cultures (Fig. 1). After the fourth day, however, a significant

Fig. 1. Proliferative response of cell cultures from spleen, popliteal lymph nodes and buffy coat after primary immunization with keyhole limpet haemocyanin (KLH) intravenously. Response expressed as: counts of tritiated thymidine incorporated into DNA with antigen/tritiated thymidine counts incorporated into DNA without antigen.

Fig. 2. Proliferative response of cell cultures from spleen, popliteal lymph nodes and buffy coat after primary immunization with KLH into the hind foot pads. Response expressed as: counts of tritiated thymidine incorporated into DNA with antigen/tritiated thymidine counts incorporated into DNA without antigen. response was regularly obtained in the spleen cell suspensions. As can be seen in Fig. 1, the capacity for this reaction persisted in the spleen, but appeared in the lymph node and peripheral white blood cells only after 2 weeks. Results of some typical experiments are presented in Table 1. On the twelfth day (Table 1), lymph node and blood cells had still not responded. On the fourteenth day there was a response. Control cultures consisting of either non-immunized rabbits or rabbits immunized with other antigens such as bovine serum albumin, brucella melitensis, or egg albumin did not show a response.

When KLH in saline was given into the hind foot pads, the initial response appeared in the regional popliteal lymph nodes (Fig. 2a). The onset of responsiveness occurred on the fourth day after administration of antigen. Two days later, a similar response was detected in the spleen and in the blood. When KLH was given into the foot pads in complete Freund adjuvant, a response (Fig. 2b) was noted as early as the second day in cells from the local lymph nodes. In this case, a response in the spleen cell cultures was observed on the fourth day and in the peripheral blood cells on the fifth day.

Proliferation of lymphoid cells has been shown to be an early feature of the immune response, which begins almost immediately after either the primary or secondary administration of antigen<sup>6</sup>. Proliferation of lymphocytes *in vitro* has also been produced by phytohaemagglutinin and other non-specific agents<sup>3,4,7</sup>, but it appears from our experience and that of previous workers<sup>5</sup> that the response of lymphocytes to antigen is specific and occurs only after previous exposure to the same antigen *in vivo*. Cells from

non-immunized animals did not respond to antigen, and so it seems reasonable to assume that the detection of proliferation in the experiments here reported can be taken as evidence of a secondary immune response and therefore of immunological memory.

Responsive cells were detected a few days after the administration of antigen in the present experiments. The nature of the events during the latent period which lead to the relatively abrupt emergence of cells capable of a specific immune response on re-exposure to antigen is not known. It is likely that after initial exposure to antigen, primarily stimulated cells undergo a number of mitoses to establish a population of immunologically competent cells which are committed to this antigen. Within this population, presumably, some cells differentiate fully to become antibody producing cells while others early acquire the capacity to respond only after re-exposure to the specific antigen. After removal from the animal and placement in tissue culture, the latter cells apparently continue in a resting stage in the absence of added antigen. It is possible that *in vivo* restimulation of such early appearing memory bearing cells by available antigen is involved in the normal development of the primary response. If this were so, a response of essentially a secondary type would form an integral part of the primary immune response. It is possible, therefore, that the cellular events described are related to the development from the early 19S or IgM antibody to the later 7S IgG variety<sup>1,8,9</sup>, especially because predominantly 7S antibodies are produced in the secondary response following most antigens<sup>1</sup>.

## Effect of the Number of Antigens on the Quantity of Cells producing Several Kinds of Antibody

DATA concerning the quantity of cells which synthesize two kinds of antibody simultaneously are contradictory<sup>1-3</sup>. The kinetics of such cells has not been extensively investigated. Accordingly, we have attempted to investigate the effect of the number of antigens used for immunization on the quantity of cells synthesizing more than one kind of antibody. For this purpose, several groups of Wistar rats were given single subcutaneous injections, in both hind foot pads, of endotoxins from *Salmonella cerro*, *S. aberdeen* and *Shigella flexneri* in different combinations. The dose of each of the antigens was 5 µg/injection. The animals were killed 5 days after the injection of antigen and cell suspensions prepared from the tissues of their popliteal lymph nodes<sup>4</sup> were assayed for antibody producing cells. The assays were carried out by techniques of motile bacteria adherence<sup>5</sup> and indirect haemadsorption<sup>6</sup>. Test antigens utilized for the first procedure were live cultures of active motile *S. cerro* or *S. aberdeen* bacteria and those used for the second procedure were small round sheep erythrocytes or large dog erythrocytes sensitized by specific antigens. In control experiments, designed to verify the specificity of the chosen tests, the cells of the animals immunized with only one antigen were checked by all three test antigens. To rule out the possibility of passive "induction" of adherence reactions, cells of intact animals treated with serum or saline extracts of lymph nodes of immunized rats have also been tested. The results of the control experiments have shown that the techniques used are of adequate specificity.

Four groups of rats, eighteen or nineteen animals each, were used in most of the experiments (Table 1).

Table 1. ANTIBODY PRODUCTION BY SINGLE CELLS OF ANIMALS IMMUNIZED WITH *S. cerro*, *S. aberdeen* AND *Sh. flexneri* ANTIGENS

Complex antigens used for immunization	No. of cells tested	No. of cells synthesizing antibody to the antigens:

<i>Sh. flexneri</i>					

\* Percentage of active cells out of cells tested.

† Percentage of double producers out of active cells.

On the basis of the available data it seems logical to draw the following conclusions. Only a small fraction of the population participates in the production of antibodies; this agrees well with the evidence of different investigators<sup>7-10</sup>. When animals are immunized with two antigens, most of the cells (99.3 per cent), in accordance with Nossal's experiments<sup>1</sup>, are found to synthesize only one kind of antibody and not more than 0.7 per cent of cells is synthesizing both kinds of antibody simultaneously. Animals immunized with three antigens, however, show a marked increase in the quantity of cells with "double activity" (2.2 per cent). These differences are statistically significant ( $P < 0.01$ ).

To eliminate the possibility that double producers are the result of methodological errors or artefacts, the cells isolated from animals immunized with different antigens were mixed. All three test antigens were added to the test mixture. Examination of 22,239 cells of this "mixed control" did not show any cell to which red blood cells and bacteria or red blood cells of two different types would attach simultaneously. Cells synthesizing three kinds of antibody have not been demonstrated. It is noteworthy that the quantity of cells producing antibody

to any of the antigens was roughly identical for all the groups tested. Thus, for example, 0.4 per cent of antibody producers to *Sh. flexneri* was found among the cells isolated from the animals immunized with *S. cerro* and *Sh. flexneri* antigens. The same quantity of active cells was detected when examining the cells of the animals immunized with three antigens.

Comparable results were obtained for determination of the quantity of cells producing antibody to *S. cerro* antigen (0.6 per cent, 0.5 per cent and 0.5 per cent). Significant differences ( $P < 0.01$ ) were observed only for the *S. aberdeen* antigen. In other words, the response to each of the antigens seems to have an independent course. This observation has been confirmed by investigations of antibody content in blood serum.

In conclusion, the available results seem to indicate that lymphoid cells are predetermined to the reaction with a specific antigen or, more likely, with a group of antigens. This conclusion is supported by the following findings: (a) production of antibody of one kind by the majority of active cells; (b) correlation between the quantity of double producers and the number of antigens injected; and (c) relative independence of the responses to each of the antigens injected.

## HAEMATOLOGY

### Stimulation by Leukaemic Sera of Colony Formation in Solid Agar Cultures by Proliferation of Mouse Bone Marrow Cells

Two papers have recently described techniques for stimulating cells from mouse haemopoietic tissue to proliferate *in vitro* in solid agar to form cell colonies. Pluznik and Sachs<sup>1,2</sup> used feeder layers of mouse embryonic cells or cell free extracts of embryonic tissues to stimulate colony formation by spleen cells, while Bradley and Metcalf<sup>3</sup> described similar colony formation by bone marrow cells when neonatal mouse kidney cells were used as a feeder layer. In the latter work the colonies were found to be aggregates of myelopoietic cells in various stages of differentiation, mixed with mononuclear cells containing varying amounts of metachromatic cytoplasmic granules.

Recently, we have found that serum from *AKR* mice with spontaneous lymphoid leukaemia is effective in stimulating colony formation by mouse bone marrow cells. Based on this observation, a survey was carried out on sera from individual normal and leukaemic *AKR* mice and on sera from other mouse strains to determine the frequency of sera with colony-stimulating activity. Single cell suspensions of bone marrow cells from pools of 2-3, two months old *C57BL* mice were prepared in equal volumes of double strength Eagle's minimal essential medium supplemented with foetal calf serum and 0.6 per cent agar in a concentration of 50,000 nucleated cells per ml. of nutrient agar medium. Volumes of 0.1 and 0.05 ml. of serum were placed in glass or plastic Petri dishes (diameter 35 mm) and immediately afterwards 1 ml. portions of the cell suspensions in nutrient agar, con-

taining 50,000 nucleated bone marrow cells, were added to each dish and allowed to gel. The dishes were then incubated at 37° C in a humid incubator gassed with 5 per cent carbon dioxide in air. Control cultures were prepared with no added mouse serum.

In cultures with added leukaemic serum, micro-colonies were visible at  $\times 40$  magnifications after two days of incubation and the colony size rapidly increased up to the sixth day of incubation, forming macro-colonies containing approximately 200 cells, after which colony growth appeared to proceed more slowly, reaching an average size of 600 cells by the tenth day. Colony counts were performed as a routine after 10 days of incubation. In addition to the macro-colonies, numerous micro-colonies were seen on all stimulated plates, but these were not counted. In control cultures, micro-colonies were observed early, but the majority of these failed to increase in size and many disintegrated as culture proceeded. Only occasionally were one or two macro-colonies observed to develop in control cultures and an arbitrary number of five macro-colonies with the 0.1 ml. serum dose was chosen as the minimum number of colonies required to be present to indicate stimulation of colony formation by added serum.

Tests of leukaemic and normal sera were run under double blind conditions, and the results obtained from these tests are shown in Table 1. Of 71 leukaemic *AKR* sera tested, 64 (90 per cent) were found to stimulate colony formation, and the average number of colonies formed with the 0.1 ml. dose was  $24 \pm 20$  ( $\pm S.D.$ ). With the 0.05 ml. dose of serum, the mean number of colonies stimulated by the active leukaemic sera was  $7 \pm 7$ . Of 30 sera from normal two months old *AKR* mice, 10 (33 per cent) were found to exhibit activity and stimulated the development of a similar number of colonies to that stimulated by leukaemic serum. Nine of 17 (53 per cent) *AKR* mice aged 7-9 months and showing preleukaemic morphological changes in the thymus were found to stimulate colony formation. In a group of 16 sera from two months old *AKR* mice carrying transplanted thigh tumours derived from primary leukaemias in four *AKR* mice, 13 (82 per cent) were found to exhibit colony stimulating activity.

Tests were also made on sera from *C3H* and *C57BL* mice. Of 42 sera from *C3H* mice aged 2-18 months, only two sera (5 per cent) exhibited colony stimulating activity. Of some interest was the fact that 16 sera from *C3H* mice with breast, lung or liver tumours were without colony stimulating activity. Of 28 sera from *C57BL* mice aged 2-20 months, 4 (14 per cent) were found to stimulate colony formation.

Table 1. ANALYSIS OF SERA FROM LEUKAEMIC AND OTHER MICE FOR COLONY STIMULATING ACTIVITY ON *C57BL* BONE MARROW CELLS

Strain	Type of mouse	Age in months	No. of mice tested	No. of sera	
				Positive	Negative
<i>AKR</i>	Normal	2	30	10 (33 per cent)	20
	Preleukaemic	7-9	17	9 (53 per cent)	8
	Leukaemic	7-12	71	64 (90 per cent)	7
<i>AKR</i>	Transplanted leukaemia	2	16	13 (82 per cent)	3
<i>C3H</i>	Normal	2-18	42	2 (5 per cent)	40
	Mammary tumours	11-15	10	0	10
	Miscellaneous tumours	12-18	6	0	6
<i>C57BL</i>	Normal	2-20	28	4 (14 per cent)	24

A detailed cytological analysis has been made of colonies stimulated by *AKR* leukaemic serum and will be reported elsewhere. In brief, the earliest colonies sampled (4-12 cells) at two days were composed mainly or entirely of large cells with ring-shaped or horseshoe-shaped nuclei, together with smaller ring or horseshoe-shaped nuclear cells and some polymorphs. Most of these cells were without metachromatic granules. From the third day, colonies also contained large mononuclear cells with a single round nucleus of mean diameter larger than  $10\mu$ .

and an irregular cytoplasmic content of metachromatic granules. After the fifth day an abrupt change occurred in the colonies which sharply differentiated them from the bone marrow cell colonies developing on cell feeder layers<sup>3</sup>. All polymorph cells and cells with ring-shaped or horseshoe-shaped nuclei disappeared and the colonies remained as pure populations of large and small mononuclear cells. The small mononuclear cells had round nuclei of mean diameter 4–5 $\mu$ , often in an eccentric location, and the cytoplasm was filled with a varying number of metachromatic granules.

From the fourth day the mononuclear cells began to develop cytoplasmic vacuolation and this vacuolation became more marked as the colonies aged. By the tenth day, when colony cell number ranged from 400 to 1,000 cells, many small mononuclear cells exhibited pyknotic nuclei or completely lacked a visible nucleus. Cellular disintegration became more marked when colonies were incubated for more than 10 days. Only the large cells with ring-shaped nuclei and the large mononuclear cells appeared to exhibit mitotic activity and the mitotic indices of both cell types were about 4 per cent between the second and sixth days of culture. Mitotic activity declined between the seventh and tenth days of incubation.

The present data suggest that a bone marrow colony stimulating factor is present in the serum of most *AKR* mice with spontaneous or transplanted lymphoid leukaemia. This may well not be an abnormal factor since a similar factor appears to be present in the sera of some normal *AKR* mice and less frequently in the sera of mice of other strains. Leukaemic sera, however, appear to contain more of this factor than does normal serum or serum from mice with other types of tumours. The myelopoietic nature of the early colony cell population is of interest since leukaemic *AKR* mice invariably show excessive myelopoiesis as evidenced by elevated levels of polymorphs in the blood, with a normal time sequence for labelling of blood polymorphs following tritiated thymidine labelling (Metcalf, unpublished data). The present serum factor may be responsible in part for this increased myelopoietic activity in leukaemic mice. In view of the development ultimately in the colonies of a pure population of mononuclear cells having some features of mast cells, however, the serum factor may not be simply a myelopoietic factor but a growth stimulant for a number of haemopoietic cell types.

Further studies are in progress to establish the precise nature of the cells in the bone marrow colonies, and to determine the chemical nature of the active factor in leukaemic serum.

## CYTOLOGY

### Morphological Changes in the Parafollicular Cells of the Rat Thyroid Glands after Administration of Calcium shown by Electron Microscopy

THE parafollicular cells named by Nonidez<sup>1</sup> are the second type of glandular cells which make up the mammalian thyroid glands. They occur along the basal (interstitial) surface of the follicular epithelium, and never face the

colloid-containing follicular lumen. Electron microscopy has shown that this cell type differs completely in ultrastructure from the follicular cells<sup>2,3</sup>. Such a morphologically distinct cell type has been assumed to have a function distinct from that of the follicular cell, that is, the production of iodine-containing thyroid hormones.

A factor which lowers serum-calcium and which is called calcitonin or thyrocalcitonin is known to be in the second group of hormones secreted from the thyroid gland<sup>4,5</sup>. A morphological investigation with the light microscope suggested that this new found hormone could be secreted from the so-called mitochondrion-rich cells of the thyroid, but the identity of these cells as the parafollicular cells could not be established<sup>6</sup>. In order to clarify a possible relationship between the parafollicular cell and the hormone concerned with calcium metabolism, we tried electron microscopy of the thyroid glands of normal and calcium-injected rats. We also looked at the thyroids of hypophysectomized rats.

In a preliminary experiment, the influence of an intravenous injection of calcium solution on the serum calcium level was observed. Calcium chloride solution which contains 10 mg of calcium ion/ml. was injected in an amount of 1.0 ml/kg of body weight into the femoral vein of each experimental rat, under slight anaesthesia with ether. Blood samples from control and experimental animals were collected and the total calcium concentration was measured by means of a flame-spectrophotometer. Changes in total serum calcium content after the injection are shown in Fig. 1. It may be noted that the concentration of calcium in the serum which immediately rose, as a result of the infusion of exogenous calcium, soon afterwards decreased gradually and had a minimum value which was far less than the normal concentration 4 h after the injection.

The parafollicular cells in the osmium-fixed preparations have already been characterized by the presence of many clear vesicles which probably contain less dense secretory substances and could be transitional from the dark secretory granules exclusively found in the Golgi area<sup>2,3</sup>. We found that the secretory vesicles increase in electron density and appear as more or less dense granules after fixation with glutaraldehyde followed by osmium tetroxide (Fig. 2). This method of preparation is effective for the examination of the functional state of parafollicular cells by electron microscopy, because the secretory granules become easily distinguishable from vesicles of the other types, such as the Golgi vesicles, the vesicular elements of the endoplasmic reticulum, and pinocytotic vesicles.

The secretory granules of parafollicular cells diminished in number after injection of calcium and reached a minimum number 4 h after the injection (Fig. 3). The

Fig. 1. Fluctuation of total serum concentration of calcium in the rats after intravenous injection of calcium chloride solution.

degree of degranulation varies considerably from cell to cell, but at this stage almost empty cells containing only two or three granules appear in a given section of the cell. Simultaneous observation of the thyroids of hypophysectomized rats indicated no morphological changes in the parafollicular cells, although the follicular cells showed a high degree of atrophy.

In Fig. 4 are histograms showing the distribution of density of the secretory granules of the parafollicular cells in each group of experiments. The population density of granules was indicated by the number of granules in a square micron of the cytoplasmic area, which was measured on fifty cells for each group by means of a planimeter on the electron micrographs magnified 10,000 times. The mean population density of normal parafollicular cells as well as those of hypophysectomized rats is about  $4.3/\mu^2$ , but it shifts to 3.4 at 2 h and 2.1 at 4 h after injection of calcium. This result indicates clearly the degranulation of parafollicular cells as a specific effect of the acute exogenous hypercalcaemia.

Fig. 2. A parafollicular cell of the normal rat thyroid fixed with glutaraldehyde followed by osmium tetroxide. A large number of dense secretory granules are contained in the cytoplasm. ( $\times 7,500$ .)

Fig. 3. A parafollicular cell of the rat 4 h after injection of calcium. The preparation procedure is the same as that shown in the above picture. Only a few secretory granules are contained, and the cytoplasm appears clear. ( $\times 7,500$ .)

Fig. 4. Histograms showing the distribution of population density of secretory granules of the parafollicular cell in each experimental group: normal control, 2 and 4 h after calcium injection, and 7 days after hypophysectomy.

This experiment suggests that the parafollicular cells are the most intimately concerned with the function of the thyroid gland which lowers the serum concentration of calcium in response to the acute administration of calcium into the blood stream. It is possible that the second thyroid hormone, that is, calcitonin or thyrocalcitonin, may be produced from the parafollicular cell.

### Pattern of DNA Replication of the Sex Chromosomes in Three Males, Two with XXX and One with XXYY Karyotype

INVESTIGATIONS of the pattern of DNA replication have shown that the X chromosomes in normal female cells exhibit marked asynchrony and one of them has a pronounced pattern of late replication. Other chromosomes differ also with respect to the time of DNA synthesis. In male cells it has been found that the Y chromosome replicates late compared with chromosomes of the 21-22 group<sup>1,2</sup>. This relatively late replication pattern of the

Table 1. MEAN GRAIN COUNTS ON Y AND CHROMOSOMES OF 21-22 GROUP

Individual	Mean Y	Mean of 21-22 group	Late replicating X chromosome
XY (A)	8.8	3.2	—
XY (B)	10.0	2.2	—
XXYY	8.2	1.4	22
XY (A)	9.1	1.0	—
XY (B)	8.2	2.0	—

Y chromosome has also been found in other mammals<sup>3-5</sup>. Investigations in patients with additional X chromosomes have shown that all X chromosomes in excess of one have pronounced late replicating patterns, similar to that of one of the X chromosomes in normal female cells<sup>6-10</sup>. As far as we know there have been only two previous references to the replication pattern of cells with two Y chromosomes. The presence of two heavily labelled presumptive Y chromosomes in an XY male was quoted as a personal communication from Castilla, Breg and Miller, in the review by Miller<sup>11</sup>. Kikuchi and Sandberg<sup>12</sup> studied replication patterns in two males with XY karyotype.

The two XY males were clinically normal on general physical examination, but above average in height; the XY male was mentally retarded and had small testes. Peripheral blood leucocyte cultures were made from these three patients by a modification of the method of Moorhead *et al.* Labelling was carried out by adding tritiated thymidine (specific activity 4.4 c./mmole), to give a concentration of 0.2 µc./ml. of culture medium, 6 h before termination. Colchicine was added 3 h before termination. Slides were stained with aceto-orcin and coated with Kodak 'AR 10' autoradiographic stripping film. When cells suitable for chromosome analysis had been photographed, the film was removed in 45 per cent acetic acid and the same cells were rephotographed. For XY individuals it was possible to distinguish morphologically the two Y chromosomes in twelve cells of one individual and in seven cells of the other. In the case of XXYY the two Y chromosomes could be distinguished in eight cells.

Grain counts were made on Y chromosomes, chromosomes of the 21-22 group, and in the XY individual on the late replicating X chromosome too. Grain counts for the Y chromosomes are reported as mean values for each individual, for the two Y chromosomes cannot be distinguished from each other in each cell. Grain counts for the 21-22 group are reported as the mean value for all four chromosomes of this group. Grain counts on the Y chromosome and 21-22 group of two normal males were used as controls. In each case ten cells were found to be suitable.

The results of grain counts in three males with two Y chromosomes and two normal control males are presented in Tables 1 and 2. In the three individuals with two Y chromosomes it was impossible to distinguish between the two Y chromosomes in each cell. It was noted, however, that in each cell the grain counts were nearly the same over both Y chromosomes, and it was therefore permissible to take a mean value for each cell. Two sources of variation contribute to the total variation encountered in the amount of labelling on the Y chromosome. Within an individual there may be variation between cells which results from differences in the stage at which they take up

labelled thymidine and from random variation. Between individuals there may be variation caused by a different pattern of labelling of their Y chromosomes.

To estimate accurately the significance of the variation between individuals the effect of different stages must be eliminated. The total grain count on the 21-22 group was used as a standard of the stage, because the size and shape of the chromosomes of group 21-22 are nearest to those of the Y chromosome. When the grain count of a Y chromosome (or mean of two Y chromosomes in the abnormal individuals) is plotted against the log of the total grain count on the 21-22 group a linear relationship emerges. It is therefore possible by analysis of covariance to eliminate stage differences from our comparison between individuals by using the log of the grain count over the group 21-22 as the correcting covariate.

When the corrected counts for Y grains were used it was found (Table 3) that the variance between individuals is greater than that within individuals (between cells), *P* between 10 per cent and 5 per cent. When, however, the individuals were divided into a group of normal and a group of abnormal individuals, their variance was not significantly different from the within group variance. From this we can conclude that, although individual differences exist in the labelling pattern of the Y chromo-

some, the differences do not appear to be related to the difference between normal and abnormal individuals.

We found that, in the three individuals with two *Y* chromosomes, both *Y* chromosomes replicate late compared with the other small acrocentric chromosomes. Counts of grains showed that this replication pattern does not differ significantly from that in normal male cells. It was found that grain counts on the two *Y* chromosomes in the three abnormal individuals fell into a homogenous group which could therefore be considered to come from one population. In addition the *Y* grain counts in each cell were homogenous. It seems, therefore, that the two *Y* chromosomes behave similarly with respect to DNA synthesis. Similar synchrony has been seen in other groups of chromosomes. Gilbert *et al.*<sup>14</sup> reported synchrony in the *A* group of chromosomes in normal and abnormal individuals, and Giannelli<sup>15</sup> reported similar findings in group *D* in a *D*<sub>1</sub> trisomic subject.

In individuals with additional *X* chromosomes, marked asynchrony and pronounced late replication of these chromosomes have been found. This late DNA synthesis of the *X* chromosomes is thought to be correlated with genetic inactivation of at least a large part of *X*, and is believed to take place during the prenatal life. It could have been suggested that extra *Y* chromosomes would also replicate late like the extra *X*. The data in this report show that both *Y* chromosomes behave in the same way and like the normal *Y*. This suggests that the mechanism of inactivation operating in the case of the extra *X* chromosomes does not apply in the case of the extra *Y*. Phenotypic effects such as the extra height and aggressiveness reported in patients with an extra *Y*<sup>15-17</sup> can therefore be related to the action of genes on the *Y* chromosome in pre- and post-natal life.

There are no comparative reports in the literature of grain counts on *XXYY* and *XXY* individuals. It was therefore impossible to draw conclusions on the basis of grain counts on the relationship between the late replicating *X* and the *Y* chromosome.

We thank Mrs. S. Bairstow and Mrs. P. Cooke for the statistical analysis and Professor P. E. Polani, Mrs. P. Cooke and Dr. F. Giannelli for reading the manuscript and for valuable suggestions. K. B. was a British Council Scholar and M. D. C. a Beit Memorial Research Fellow.

## PATHOLOGY

### New Carcinogenic Naphthalene and Biphenyl Derivatives

As part of an extensive series of tests for carcinogenic activity a number of naphthalene and biphenyl derivatives of potential or actual commercial use were examined. The practicability of standardizing the methodology of large scale quantitative bioassay of many different compounds was also investigated.

The procedures consisted of oral administration by gavage five times in a week for 52 weeks (260 doses) of several concentrations of test compound to sixty male and female Fischer rats. The animals were observed an additional 26 weeks unless their condition required earlier killing. Chemicals were dissolved or suspended in "steroid suspending vehicle" (9 g of sodium chloride; 5 g of sodium carboxymethylcellulose 7 LP; 4 ml. of polysorbate 80; 9 ml. of benzyl alcohol, and water to 1 l.). The amount of the compound tolerated was determined in three to five rats/dose concentration for a 2 month period. The definitive tests were based on these results.

We report here the salient findings obtained at one dose concentration, one-third of the maximally tolerated, with four compounds (Table 1). In male rats 171 to 218 doses of 10 mg of 3-methyl-2-naphthylamine, originally proposed as a substitute for 2-naphthylamine, caused chiefly tumours as well as sessile adenomatous growths of the lower intestinal tract, in the ileum and the colon. In addition, papillomas of the skin and squamous cell carcinoma of the ear duct developed. In female animals, after 76 to 118 doses of 10 mg and a latent period from 126-191 days, adenocarcinoma of the mammary gland was found in virtually all animals<sup>1</sup>. This compound, thus, is potent for the breast, although the female Fischer rat is less susceptible than other albino strains as, for example, the Wistar or Sprague-Dawley rat<sup>2-5</sup>.

The related 3-nitro-2-naphthylamine was less active. Both males and females receiving doses of 10 mg had tumours in the forestomach after 555 days (males) and after about 420 days (females). Several other aromatic nitro compounds gave a similar result<sup>6,7</sup>. In females the mammary gland was also affected. 1,2-Dichloro-3-nitronaphthalene was still less active, because 260 doses of 30 mg led to two fibromas and one pituitary adenoma, possibly spontaneous lesions, in males, and four mammary gland tumours in females after 500 days.

3,3'-Dimethoxybenzidine, or dianisidine, after 260 doses of 10 mg gave tumours in male and female rats at a variety of sites (skin, gastrointestinal tract, breast, ear duct) as early as 293 days. Most of the lesions were seen in rats autopsied after 500 days of treatment. This compound, which is of industrial importance<sup>8</sup> as a dyestuff intermediate, is therefore definitely carcinogenic. Gehrmann *et al.*<sup>9</sup> found it inactive in dogs, while Pliss<sup>10</sup> noted that the dimethoxy derivative was less active than benzidine itself.

In the entire series, 660 simultaneous control animals were used. The tumour incidence in this group was recalculated for each fifteen male and fifteen female rats to permit ready reference to the experimental groups discussed here. Detailed findings and description of the pathology will be published elsewhere.

In conclusion, the carcinogenic activity of several naphthalene and benzidine derivatives was determined by quantitative tests in rats. 3-Methyl-2-naphthylamine readily evoked tumours of the lower intestinal tract in males and is therefore a new tool to produce and investigate this lesion, so important in man. In females this compound is a potent mammary carcinogen. 3-Nitro-2-naphthylamine gave mainly tumours of the forestomach. 3,3'-Dimethoxybenzidine induced tumours at several sites. 1,2-Dichloro-3-nitronaphthalene was only slightly tumorigenic.

Table 1. TUMOURS INDUCED BY 2,3-SUBSTITUTED NAPHTHALENES AND BY DIANISIDINE

Compound	Daily dose (mg)	Sex	Survival (days)	No. of lesions	No. of lesions*

### Neoplastic Transformation of Rat Embryo Cells by Simian Papovavirus SV<sub>40</sub>

SV<sub>40</sub> virus manifests its oncogenic action only in hamsters<sup>1</sup> and in mastomys<sup>2</sup>. There are, however, reports of its transformation *in vitro* of cells of hamsters<sup>3</sup>, mice<sup>4</sup>, rabbits<sup>4</sup>, pigs<sup>4</sup>, cows<sup>5</sup>, monkeys<sup>6</sup> and humans<sup>7</sup>. The purpose of our investigation was to determine whether the SV<sub>40</sub> virus possesses the ability to transform rat cells *in vitro*.

A monolayer of Wistar rat embryo skin-muscle cells grown in Povitskaja bottles (100 ml.) was infected with SV<sub>40</sub> virus using large plaque (Rh-2 A-426) and small plaque (strains No. 128 and 130) variants of this virus<sup>8</sup>. Medium 199 supplemented with 10 per cent bovine serum was used as the maintenance medium. The medium in infected and control cultures was changed once or twice a week. Eighteen days later the cells were collected with versene solution and put into tubes. The tube tissue

cultures were maintained, as shown above, without subcultivation. The results obtained are presented in Table 1.

In test No. 1, beginning from the fourth week, foci of epithelium-like cells were found which were not sharply delimited from the surrounding fibroblast-like cells. The foci (1-3 per tube) soon became multilayers. By the end of the third month the fibroblast-like cells degenerated, but the foci remained and increased in size, acidifying the medium intensively. The subcultivation of such foci from individual tubes presented no difficulties; two cell lines—426/20 and 130/20—were established. Such phenomena were not observed in any of the control tubes.

In test No. 2 the features of cell transformation were different. On the fourth week multiple round-shaped cells appeared in the infected tissue cultures; they were disseminated in the monolayer or formed multilayer foci. The appearance of giant cells was characteristic of these cultures. The infected tissue cultures acidified the medium intensively. By the end of the second month of infection the number of round-shaped cells considerably decreased, only large multilayer aggregates of such cells remained, which could be recognized grossly. As a result of the subcultivation of such tissue cultures from individual tubes two cell lines were established—426/25 and 128/25. In control tissue cultures such changes were not seen, and the monolayer degenerated in the second or third month of the experiment.

The testing of culture fluids from infected cultures in green monkey kidney cell culture showed that the virus was present in trace amounts during the first 2-4 weeks and then disappeared.

The demonstration of the tumour antigen in the cells of established rat-cell lines formed important evidence of the specificity of described transformative changes of rat cells. Five per cent extract of cells 426/20 and 426/25

Table 1. TRANSFORMATIVE ACTIVITY OF SV<sub>40</sub> VIRUS IN SKIN-MUSCLE RAT EMBRYO CELL CULTURE

\* Numerator—number of tube tissue cultures with phenomena of transformation.

Denominator—number of tissue cultures remaining till the end of the observation period.

reacted specifically in complement fixation test with an active pool of hamster sera from animals bearing tumours induced by  $SV_{40}$ , but did not react with hamster sera from animals bearing tumours induced by polyoma or Rous sarcoma viruses.

By means of the direct method of fluorescent antibody, using the conjugate of serum globulin (obtained from hamsters bearing  $SV_{40}$  tumours) with fluorescein isothiocyanate, the presence of  $SV_{40}$  tumour antigen was revealed in the nuclei of 100 per cent of line 426/20 cells (other lines were not tested). The nuclei of various control culture cells not infected with  $SV_{40}$  showed no distinct fluorescence.

Wistar suckling rats 3–5 days old were inoculated with the cells of lines 130/20, 426/20 and 128/25 (eighth to tenth passage) (using  $3 \times 10^6$ – $5 \times 10^6$  cells subcutaneously). None of the twenty animals developed tumours during an observation period of 4–6 months. When hamsters were inoculated into the cheek pouch with about  $10^6$  cells of line 426/20, nodules 0.5 cm in diameter were formed at the site of inoculation 6–8 days after inoculation, which disappeared 3–4 weeks later. A histological study of such nodules showed that they had the features of spindle-shaped cell sarcoma (I. S. Levenbook).

The data obtained point to the ability of  $SV_{40}$  to induce neoplastic transformation of rat cells. Morphological features of the initial stages of transformation were not identical in the two tests described above. This may be accounted for by different cell composition of the tissue cultures used in these experiments.

The absence of tumorigenicity of transformed cells in rats is correlated with the absence of oncogenic activity of  $SV_{40}$  in these animals. Similar data were obtained in this laboratory when the transformation of mouse embryonic cells of  $C_3HA$ ,  $CC_{57}Br$ , and  $C_{57}BL$  mice by  $SV_{40}$  virus was studied (N. N. Dodonova *et al.*, in the press).

### Spontaneous Neoplastic Transformation of Mouse Heart Tissue *in vitro*

WE have examined the possibility that cells derived from heart tissue might undergo spontaneous neoplastic transformation less rapidly than other tissue, the heart rarely being a site of primary malignancy.

Fibroblasts from rat myocardium grown in a chicken plasma clot under nitrogen produced tumours when they were implanted in rats, although control cultures did not<sup>1</sup>. Cell strains derived from mammalian heart tissue are rare, and even the cells thought at first to have been derived from cynomolgous monkey heart<sup>2</sup> and reported to produce fatal tumours when injected into pretreated Wistar rats<sup>3</sup> were later thought to be a line of human heteroploid cells

similar to HeLa cells that had contaminated the culture and overgrown the monkey heart cells<sup>4</sup>.

In the present experiments, hearts were excised from anaesthetized strain A mice (20 days old and free from polyoma). Each heart was washed in warm saline, minced in a few drops of saline, and centrifuged and rewashed several times. The tissue was suspended in a variety of growth media: medium 199 and 10 per cent calf serum; Puck's medium and 15 per cent calf serum; and basal medium Eagle with 15 per cent foetal calf serum (BME). One heart was used with each medium. Equal portions of each heart were placed in each of four roller-tubes with 2 ml. of medium. Cells from trypsinized heart tissue were also used. The tubes were incubated at 37° C in a roller drum at 12 r.p.h.

The fragments attached within 12 h of inoculation and the volume of medium was increased to 3 ml. Cells obtained by trypsinization attached very poorly and failed to grow progressively. Outgrowths from the fragments began in 2–4 days and were typical fibroblasts, radial in appearance with a mixture of large, granular cells. The latter disappeared in about 2 weeks, but a number of isolated cells remained. Medium 199 and Puck's supported steady growth less successfully than BME and were discarded. The trypsinization of cultures grown in BME was only partially successful in that the majority of cells were lost and the growth of the surviving cells decreased.

The fragments in BME grew in all four test-tubes; the cultures were re-fed three times each week. Acidity caused the appearance of cellular processes and the more isolated cells died. When growth was allowed to continue, additional layers of cells formed; but the cells were for the most part arranged parallel to one another. After a month the fragments usually detached from the glass and, if small, reattached and flattened out. Extensive growth occurred in areas where the original fragment had been located. Definite networks, typical of fibroblast growth, were often seen where there were few cells. Within 4 months the cultures were growing steadily and rapidly and extended up the sides of the 8 oz. "gem oval" bottles. Growth became so heavy after 3 weeks that several layers of cells peeled off in sheets. Cells would survive mechanical or enzyme removal from the glass surface. For subculturing, a monolayer was mechanically dispersed and divided between as many bottles as needed. Although cloning was not tried, a colony of ten cells could survive and grow in a small culture vessel (Fig. 1).

Strain A male mice given 1.25 mg of cortisone acetate 24 h previously were injected with cultures 4–5 months old (fifteen subcultures). All ten animals injected subcutaneously with at least  $3 \times 10^6$  viable cells developed tumours. Tumours appeared approximately 3 weeks after inoculation and grew at a steady rate; the tumours afterwards grew in unconditioned mice. Six cortisonized mice which received  $10^6$  cells and ten untreated mice injected with  $10^6$ – $3 \times 10^6$  cells developed no tumours during the 5 months after injection. The failure of the cell culture to grow in unconditioned hosts may be associated with the acquisition of new antigens by the transformed cells or with the persistence of calf serum proteins on the cell surfaces.

Microscopic examination of tumour sections (Fig. 2) showed features consistent with a highly malignant tumour: solid masses of the polymorphous type of mesenchymal tissue with large and small spindle cells, and large and occasional giant round cells. Ordinarily fibroblasts from mice, if they have undergone malignant transformation, result in classic spindle cell sarcomata when reinjected into mice<sup>5</sup>. The mesenchymal tumours, although they contained giant cells possibly associated with rhabdomyosarcoma, are difficult to classify properly because of the lack of definite striations. Even tumours of human soft tissue, which have been intensively investigated, are not easily diagnosed<sup>6</sup>; and the proper identi-

Fig. 4. Metaphase plate of cell with fifty-four chromosomes, two of which are metacentric.

fication of these tumours must be considered difficult or even impossible.

When the tumours appeared 6 months later, chromosome preparations were made on cultured cells by the usual squash and air dry techniques; slides were stained with 0.5 per cent aceto-orcein<sup>7,8</sup>. Chromosomes of 100 complete metaphases were counted. At first the chromosome number varied from the middle fifties to more than one hundred with a dispersion of chromosome numbers and no significant peak, although there was an indication of a slightly larger number of cells with chromosome numbers in the hypotetraploid range (Fig. 3A). Chromosome readjustment continued (Fig. 3B), characterized by heteroploidy with a broad mode of 74–80 chromosomes. In 25 per cent of the cells, one or more metacentric (Fig. 4) or minute chromosomes were found. Most cells, however, had all telocentric chromosomes.

The chromosomal instability of mouse cultures in the early stages of *in vitro* manipulation is well known<sup>11</sup>. There is evidence that selection is still going on within this population, thus providing evidence for a gradual replacement of normal karyotypes with karyotypes containing alterations. It is still not clear whether this readjustment of the cells indicates transformation, because neoplastic transformation may or may not be associated with gross changes in chromosomes.

No conclusion can be drawn about the cause of the cytological and neoplastic transformation which occurred spontaneously within 4 months. Medium added to the cells with or without periodic transfer resulted in pulses of growth stimulation as indicated by the rise in number of dividing cells. Nevertheless, a period of cell damage may

have ensued as a result of the decomposition of dead cells and the formation of metabolic waste materials. Under some circumstances many purines and pyrimidines, including adenine, produce mutations in bacteria<sup>9</sup> and in other circumstances cause chromosome breakage<sup>10</sup>. As a result of cell degeneration or disintegration, abnormal purines and pyrimidines may be produced and may act as mutagens.

### Activity of Aspartate Transcarbamylase in Mammary Tumours induced by 7,12-Dimethylbenzanthracene in the Rat

It has been shown that all biosynthetic reactions involved in the formation of ribonucleic acids (RNA), proteins and phospholipids, become accelerated in rapidly proliferating tissues. This requires, however, the presence of related precursors; in the case of an increased synthesis of RNA, the presence of pyrimidine bases and ribose. Beaconsfield *et al.*<sup>1</sup> demonstrated the existence of a direct correlation between the extent of RNA synthesis and ribose formation by way of the oxidative pentose phosphate cycle. Similarly, an increase of RNA synthesis must be accompanied by an increase in the synthesis of pyrimidine bases. The first step in the pyrimidine synthesis is the transformation of the carbamoyl group from carbamoyl phosphate to L-aspartic acid, forming ureidosuccinic acid. This reaction is catalysed by the irreversibly acting aspartate transcarbamylase (ATC).

Several authors suggested a correlation between ATC activity and the rate of cell growth and cell division. Calva and Cohen<sup>2</sup> observed an increase of ATC activity in the regenerating rat liver which became normal again when the phase of regeneration finished. In the rapidly growing Novikoff hepatoma the ATC activity is also higher than in the surrounding normal liver tissue<sup>3</sup>. Kim and Cohen<sup>4</sup> found that, compared with the adult liver, the ATC activity in the foetal rat liver is increased by a factor of between five and six. This value decreased to the level of adult liver within about 20 days after birth. These findings point to the existence of direct correlation between the ATC activity and the RNA synthesis and, consequently, the cell growth and cell division.

This correlation can best be demonstrated in tissues of the same origin which may show a tendency to positive or negative growth depending on the treatment given. The mammary carcinomata of the female rat induced experimentally by Huggins<sup>5</sup> are suitable models in this relation. Without any treatment these tumours usually grow very rapidly, but regress under the influence of hormones from the opposite sex. For the purpose of these experiments we induced mammary carcinomata in female Sprague-Dawley rats. At intervals of 10 days the animals were fed with three doses of 10 mg of dimethylbenzanthracene (DMBA) dissolved in sunflower oil<sup>6</sup>. Carcinomata developed in most cases within 60–80 days of the first application of DMBA. About 50 per cent of all carcinomata showed a rapid growth and this was followed up by continuous measurement of the size of the tumours. In estimating the size of the tumours two diameters were measured perpendicular to each other, multiplied together and plotted against time. A straight line drawn through the points for a period of 2 weeks gives a mean tumour growth rate for this time. The tangent of the ascending angle  $\alpha$  of this line is a measure of the rate of growth or regression. This is defined as the change of the product of the two tumour diameters obtained during a period of 2 days. A positive angle indicates a tendency to increased growth, a zero degree indicates stagnation, and a negative angle a regression of the tumour growth (Fig. 1).

Regression of mammary cancer can be achieved by the administration of appropriate dosages of testosterone. The animals were given doses of 3.0 and 6.0 mg of testosterone propionate/kg body weight twice a week, respectively. This dose regime inhibited the growth of the mammary carcinomata induced in rats by DMBA<sup>7</sup>. The therapeutic effect of testosterone must inevitably imply a reduction in the requirement for RNA, and thus for the corresponding precursors, which should result in a lower activity of ATC in stagnating or regressing carcinomata. We therefore investigated the activity of ATC in growing mammary carcinomata and such carcinomata as showed stagnation or regression when treated with testosterone.

Table 1. RELATIONSHIP BETWEEN THE TENDENCY OF GROWTH OF MAMMARY TUMOURS AND THE ACTIVITIES OF ATC AND GOT

Ascending angle (in degree)	ATC (nmoles/mg h)	GOT (nmoles/mg min)	Testosterone (mg/rat twice a week)
-76	48	-	0.5
-65	-	62.7	1.0
-64	220	-	0.5
-64	216	-	0.5
-63	228	68.6	0.5
-59	159	47.0	0.5
-56	232	-	0.5
-53	63	-	0.5
-40	177	-	0.5
-37	178	30.2	1.0
-25	77	56.7	0.5
± 0	124	35.7	1.0
+26	265	40.6	-
+27	463	74.3	-
+35	383	67.4	-
+36	-	58.3	-
+38	349	108.0	-
+38	463	43.1	-
+50	424	60.5	-
+50	-	58.0	-
+50	-	89.5	-
+54	-	28.2	-

As a parameter of the amino-acid and protein metabolism, the activity of glutamic-oxalacetic transaminase (GOT) was investigated and compared. The activity of the enzymes was measured on excised tumour tissue. The tissue was homogenized in 0.14 molar potassium chloride (1:3) three times for 20 sec in an 'Ultra-Turrax' and centrifuged for 30 min at 17,000*g*. The supernatant was diluted with a solution of potassium chloride corresponding to the expected enzyme activities.

The activity of ATC was determined according to the method of Koritz and Cohen<sup>8</sup>, except that a 0.5 per cent solution of sodium diphenylamine-*p*-sulphonate was used instead of a 1 per cent solution. The activity was expressed as the specific activity in nmoles/mg h. The GOT activity was determined spectrophotometrically according to Bergmeyer and Bernt<sup>9</sup> and recorded as the specific activity (nmoles/mg min). Measurements were also made of the increase of oxalacetate with time which was then reduced by an additional indicator reaction with reduced nicotinamide-adenine dinucleotide (NADH<sub>2</sub>) and malic dehydrogenase to malate. The consumption of NADH<sub>2</sub> was proportional to the amount of oxalacetate present, and the decrease was followed up at 340 nm. The protein content of the samples was determined according to the biuret method.

The results of the measurements are summarized in Table 1. All animals injected with 3.0 mg or 6.0 mg of testosterone/kg of body weight showed a stagnation or regression of tumour growth. The levels of ATC activity of these tumours are clearly lower than those of growing carcinomata. When the values for the activity of ATC were averaged for both testosterone-treated and untreated animals mean values of  $156.4 \pm 68.6$  and of

Fig. 1. Growth of mammary tumours. *a*, Growing tumour (without treatment with testosterone); *b*, regressing tumour (treatment with 3.0 mg testosterone propionate/kg of body weight twice a week). The arrow indicates the start of treatment with testosterone.

391.2 ± 76.5 nmoles/mg h, respectively, were obtained. The two results are significantly different with  $P < 0.0027$ , whereas no significant differences were detected in the GOT activities of both groups—the averages 50.2 ± 15.3 for animals treated with testosterone and 62.8 ± 23.7 nmoles/mg min for untreated animals. The results thus confirm the existence of a correlation between the activity of ATC and the extent of RNA synthesis, whatever the action of testosterone may be. Its mode of action may be interpreted in terms of the theory of Monod and Jacob<sup>10</sup> as a negative effector, but also according to Koshland<sup>11</sup> as a regulator of the active site of an enzyme.

## RADIOBIOLOGY

### X-Radiation Sensitivity of DNA—Ability to form Specific Molecular Hybrids with Isologous mRNA

THE basic functions of cell DNA are priming of DNA synthesis and priming of RNA synthesis. The radiation damage of the first is believed to be closely related to mutant formation and cell reproduction, and that of the second to genetic determination and regulation of intracellular metabolic processes. Recent investigations of these basic functions of DNA resulted in profound changes in the existing research practice and directed the development of radiation biochemistry of DNA from an almost purely phenomenological ground to a more causal approach. Although a relatively clear picture of cell molecular biology does exist, conflicting results are still obtained about the activity of the DNA primer, so far as its radiosensitivity against ionizing radiation is concerned.

Some authors report a negligible effect of radiation on priming activity of DNA in a DNA-polymerase system up to 10 kr. X-rays<sup>1</sup>. Others consider DNA synthesis to be a process that, on the contrary, is not suppressed but rather, within certain X-ray dose limits, is stimulated by ionizing radiation<sup>2</sup>.

Recently Harrington published data showing remarkably high sensitivity to X-rays of DNA priming properties assayed by a DNA-polymerase system. A dose of 500 r. reduced the activity of the DNA to about 50 per cent<sup>3</sup>; the priming activity of DNA for RNA polymerase was much less affected.

We have investigated radiosensitivity of another macromolecular property of DNA, that is the ability to form genetically specified molecular hybrids with correspondent messenger RNA. We used the nitro-cellulose membrane filter technique of Nigaard and Hall<sup>4</sup>. Our experimental results reveal a very steep slope in the dose-response curve (Fig. 1). Obviously, "complementarity" remains unchanged for a certain increase in X-dose, until a critical point of chemical "defects" accumulation is reached and then there is a sharp drop in hybrid formation. This brings the values of irradiated samples to those of the unhybridized controls.

Fig. 1. Dose dependence of DNA/mRNA hybrid formation on X-irradiation of DNA. x, Irradiated DNA of *E. coli* B + mRNA of *E. coli* B; Δ, DNA of *E. coli* B + mRNA of *E. coli* B (non-hybrid); ●, DNA of *B. subtilis* + mRNA of *E. coli* B. Double stranded DNA from *E. coli* B was irradiated in citrate buffer (pH 7.8) at 4° C in a concentration of 1,200 μg/ml. After irradiation the DNA samples were re-precipitated with ethanol. The hybridization experiments were performed for 210 min at 78° C according to Nigaard and Hall<sup>4</sup>. RNA labelled with phosphorus-32 was obtained by means of a 5 min pulse with phosphorus-32 during the exponential stage of growth. The quantitative analysis of hybrid complex formed was carried out after alkaline hydrolysis and ribonucleotide separation on 'Dowex' 1 × 8. Irradiation: 200 kV, 20 m.amp, 0.5 aluminium 600 r./min. Two controls were used for background determinations: *E. coli* DNA + *E. coli* RNA without incubation at 78° C and *E. coli* RNA + *B. subtilis* DNA with incubation at 78° C for 210 min. In both these controls no more than 15 per cent incorporation was detected.

It is tempting to assume that the nearly horizontal part of the curve corresponds to a relative reversal of DNA-mRNA complex formation. It may be possible from these data to determine the number of breaks in the DNA which may be sustained without affecting the genetic capacity of the DNA. Once this damage has been exceeded there would theoretically be no chance for repair because of impossibility of complementation.

## PHYSIOLOGY

### In vitro Investigation of Resting Muscle Membrane Potential in Prewanling and Weanling Rat

CHANGES have been reported in muscle electrolytes with age<sup>1</sup>, and several laboratories throughout the world have reported similar changes<sup>2-5</sup>. From birth to maturity the sodium and chloride content in a unit muscle mass decreases while the potassium increases. These changes are often interpreted as a function of increasing muscle

cell size and a decreasing extracellular space in the muscle.

The sodium and chloride content was shown to be greater than the potassium content of the rat gastrocnemius at 1 day of age and by 45 days this pattern was reversed<sup>6</sup>. Similar findings have been reported for the rat semimembranous muscle<sup>7</sup>. Both laboratories demonstrated that even with these changes in electrolyte content the intracellular potassium concentration is constant with age<sup>6,7</sup>.

The resting membrane potential was reported to be low in the muscles of newborn rats and fully developed by one month of age<sup>7</sup>. In view of this work, and the failure to find significant changes in intracellular potassium<sup>6,7</sup>, it seemed pertinent to determine the resting membrane potential in muscles taken from rats during the first month of life. It is the purpose of this paper to report our findings<sup>8</sup>.

The resting membrane potentials in 10–17 and 24–27 day old rats (Houston Cheek–Jones) were measured *in vitro* with conventional electronic equipment, silver–silver chloride electrodes and Ling–Girard micropipettes. The hind limb of the rat was removed, placed in a chamber and perfused with a buffered Ringer solution<sup>9</sup>, and aerated with 95 per cent oxygen and 5 per cent carbon dioxide. After 15–30 min incubation, penetrations were made at random in the gastrocnemius muscle. In the usual case twenty-five to fifty penetrations were made into each muscle. The mean obtained from these penetrations represented the resting membrane potential for that muscle.

Table 1

Age	No. of animals	Resting muscle potential $\pm$ S.E.	Total penetrations	P
10–17 days	7	36.63 $\pm$ 3.43	283	<0.001
24–27 days	7	67.76 $\pm$ 2.13	315	

Table 1 gives the data and statistical analysis. The gastrocnemius muscles of the younger rats show resting membrane potentials significantly lower than the older rats. The usual value of resting membrane potential for excised muscle from mature rats is about 70–75 mV<sup>8</sup>; the muscle resting membrane potential of 24–27 day old rats may not yet be at full potential. The change in resting membrane potential with age cannot be explained on the basis of potassium changes. It has already been reported that intracellular potassium does not change with age<sup>6,7</sup>, and in our investigation the external potassium was held constant. It is concluded that the resting membrane potential of the gastrocnemius muscle from young rats is significantly reduced relative to that from older animals.

## Measurement of Angiotensin II in Blood

Khairallah and Page<sup>1</sup> have tried our method<sup>2</sup> for measuring angiotensin in blood and report almost complete loss of added angiotensin as well as the production of a new vasopressor substance during chemical extraction. Because these results differ from previous experience, the method has been reassessed to find out whether such differences are inherent in the technique, or are caused by their different application of the technique. Repetition of the previously reported control experiments<sup>2</sup> has confirmed our original results.

The criticisms by Khairallah and Page<sup>1</sup> can be summarized in two points as follows. (1) Losses of angiotensin occur sequentially in all steps of the extraction procedure with a cumulative loss of more than 80 per cent of the tritium label of tritium incorporated into angiotensin after its addition to blood. (2) Regardless of the losses occurring in the isolation procedure, a large part of the vasopressor material recovered is not angiotensin II, but is a lipid substance formed by hydrolysis of blood components by the hydrochloric acid used in the extraction procedure.

Khairallah and Page support their conclusions with evidence of recovery of a non-angiotensin lipid vasopressor material from all samples of blood, arterial and venous, as well as blood from an anephric patient (the latter case certainly being conclusive, because, theoretically, angiotensin should not be found in the absence of the kidneys). These observations are a dichotomy, which they note by quoting our categorical statement that no vasopressor material has ever been found in peripheral venous blood; nevertheless, they did not consider that their findings of vasopressor in all blood samples suggested a possible difference in their application of the same method.

Loss of angiotensin during isolation can occur with the multiple transfers of small volumes, but the loss by Khairallah and Page of 45 per cent of the tritium incorporated into angiotensin through trapping in the red cell mass during initial filtration is excessive and has not been our experience or that of Boucher<sup>3</sup> or Paladini<sup>4</sup>, who also precipitate the blood with ethanol and have a total recovery of 65 per cent to 95 per cent of added angiotensin. This difference could reflect too great a reliance on the stability of the tritium label by Khairallah and Page (our own experience has shown about 40 per cent spontaneous dissociation of the tritium incorporated into angiotensin), or it could be caused by inadequate washing of the precipitate during filtration.

The isolation of a lipid vasopressor substance by Khairallah and Page is a new finding; they say that this substance is probably formed by protein hydrolysis with the hydrochloric acid used in the extraction. In their investigations they titrated the concentration of hydrochloric acid in their solutions and found it to be 12.0 moles/l. We cannot explain this concentration, because the method calls for the addition of 0.5 ml. of concentrated hydrochloric acid with a minimal solution volume of 5.0 ml. Our calculation of 0.5 ml. of concentrated hydrochloric acid (37 per cent, specific gravity 1.192) in a 5.0 ml. volume is 1.219 moles/l., and the measurements of the acid molarity of extracting solutions in our laboratory have varied from 0.8 to 1.4 molar hydrochloric acid. It is difficult to know how Khairallah and Page achieved a concentration of 12.0 moles/l. of acid if the details of the technique are followed, for a concentration of 12.0 molar hydrochloric acid would require 4.95 ml. of acid in a 5.0 ml. volume, or more than eight times the amount of acid that is added.

To determine the effect of hydrochloric acid on angiotensin, we have repeated experiments with addition of hydrochloric acid to angiotensin solution to equal 1.2 molar and 12.0 molar concentration when reduced to a 5.0 ml. volume by evaporation on a steam bath at 80° C. The angiotensin recovery from the 1.2 molar solution was

98 per cent while only 11 per cent was recovered from the 12.0 molar acid solution. From this work, we agree with Khairallah and Page that 12.0 molar acid will destroy angiotensin, and could well hydrolyse other substances to produce many products, any of which could have vasopressor activity, but this point seems unrelated to the present problem because the technique calls for a maximum concentration of 1.2 molar hydrochloric acid which has not been found to destroy angiotensin.

The constancy of our own results in over 1,500 assays as well as duplication of the method by other groups (personal communications from H. G. Langford and E. Yendt) suggest that the differences found by Khairallah and Page are due to variations in their application of the technique.

### Metabolic Differentiation of the Anterior and Posterior Latissimus Dorsi of the Chick during Development

FAST and slow contracting mammalian muscles differ considerably in their biochemical properties, for example, in their enzyme activity, reflecting especially different quantitative proportions of glycolytic (extramitochondrial) and respiratory (mitochondrial) systems<sup>1</sup>, ATPase activity of myosin<sup>2</sup>, ionic content<sup>3,4</sup> and many other biochemical characteristics. Avian muscles are especially suitable for the investigation of biochemical differences of fast and slow muscle fibres, as whole muscles consist exclusively of each type of fibre<sup>5,6</sup>. Little is known of the metabolic differences between fast and slow muscle fibres of birds in which, unlike mammalian muscle fibres, there are also basic structural and electrophysiological differences of fast (phasic) and slow (tonic) muscle fibres, which differ as in frogs according to "fibrillen" or "felderstruktur"<sup>6,7</sup>, focal or multiple innervation, sensitivity to acetylcholine<sup>8</sup> and capacity for long-term contraction<sup>9</sup>. Both fast and slow contracting mammalian muscles are phasic and do not show such basic structural and electrophysiological differences.

The investigation of metabolic differences in the fast posterior latissimus dorsi and the slow anterior latissimus dorsi and their ontogenetic development should suggest whether the metabolic differences reveal a uniform pattern. In order to obtain some basic data on differences in energetic and protein metabolism in these two types of muscles, the differences in the amount of glycogen, proteins of the myofibrillar-nuclear and sarcoplasmic fractions, ribonucleic acid content and proteolytic activity in anterior and posterior latissimus dorsi of chicken (Leghorn) were examined during ontogenetic development.

The muscles were homogenized in 0.1 molar potassium chloride, and RNA<sup>10</sup> and proteolytic activity<sup>11</sup> were determined in the homogenate. The content of proteins in the myofibrillar-nuclear fraction (10 min at 1,000g) and the sarcoplasmic fraction (containing also mitochondria and sarcoplasmic reticulum) was determined by the biuret method. Glycogen was determined by a modification of the anthrone method<sup>12</sup>.

Fig. 1 shows that by the first day after hatching the glycogen content is greater in the posterior latissimus dorsi. Later the glycogen content somewhat decreases in

this muscle, but it remains at greater concentrations during development. The sarcoplasmic fraction is the same percentage of the total nitrogen in anterior and posterior latissimus dorsi of a 20-day-old embryo; its relative amount decreases later in both muscles. Anterior and posterior latissimus dorsi of older animals differ considerably in their degree of proteolytic activity; the anterior exhibits greater proteolytic activity in both sarcoplasmic and structural protein fractions<sup>13</sup>. Proteolytic activity in 20-day-old embryos and in 1-day-old animals is high in both muscles. It decreases later in both muscles, but more so in the fast posterior latissimus dorsi (Fig. 1). It can be seen from Fig. 1 that (a) reciprocal relations exist between concentrations of glycogen on the one hand and of RNA and proteolytic activity of muscles of older animals on the other, and (b) the differences in glycogen content are already established on the first day of life, whereas the differences in RNA content and proteolytic activity are established progressively during later development. RNA content of the anterior latissimus dorsi is greater by 40 per cent, and proteolytic activity greater by 200 per cent, than that in the posterior latissimus dorsi of 1-month-old animals. These differences, however, are established relatively late.

The relatively larger concentrations of RNA and proteolytic enzymes in the slow anterior latissimus dorsi would then suggest a faster turnover of proteins in slow muscles, probably related to the long-term maintenance metabolism

Fig. 1. Developing chick muscles. (A) Contribution of myofibrillar-nuclear (white columns) and sarcoplasmic (hatched columns) fractions to total proteins in muscles; (B) content of glycogen (percentage wet weight); (C) content of RNA (mg/100 mg of protein); (D) proteolytic activity (μg of tyrosine liberated/mg of protein). Each value is the mean from six animals. PLD, Posterior latissimus dorsi; ALD, anterior latissimus dorsi.

required for posture and maintenance of tension. A quicker rate of incorporation of amino-acids into proteins has indeed been found in both, the slow mammalian and the slow (tonic) avian muscles (work to be published by Gutmann and Hájek).

Glycogen concentrations are higher in the adult fast mammalian<sup>4</sup> and the fast (phasic) muscle fibres of birds and this apparently corresponds to the adaptation of the fast muscles, utilizing especially glycolytic mechanisms. Contrary to chick muscles, glycogen contents in fast and slow muscles of rats are equally high post-natally; differentiation occurs between 11 and 14 days after birth<sup>4</sup>. The differences in development of glycogen concentrations between fast and slow mammalian and fast (phasic) and slow (tonic) avian muscles are apparently related to the relatively later maturation of the motor system in rats.

The data suggest that differentiation may involve two different mechanisms, one essential for the fast muscle and reflecting a predominance of glycolytic processes, the other essential for the slow muscle and reflecting a faster turnover of proteins. It appears that the basic pattern of the two types of muscles is of a general nature and applies to the muscle of both birds and mammals.

### Electrolyte Imbalance as the Mechanism for Inert Gas Narcosis and Anaesthesia

THE mechanism by which the volatile anaesthetics induce narcosis and anaesthesia remains the subject of speculation. Similarly, there has been much controversy concerning the mechanisms by which raised pressures of air or the chemically inert noble gases xenon, krypton, argon, neon and helium produce euphoria or loss of consciousness. Among the possibilities considered which could interfere with cerebral electrical activity have been a histotoxic hypoxia, depression of metabolism, membrane stabilization or block, interference with the sodium pump mechanism, increased production of inhibitor substance, interference with adenosine triphosphate production<sup>1</sup> and the formation of clathrates<sup>1-6</sup>.

There is, however, agreement that the site of action is at polysynaptic sites in the central nervous system, caused by interference with synaptic transmission rather than on propagated action potentials<sup>6,7</sup>.

McIlwain<sup>8</sup> has suggested a hypothesis by which the biochemical and physical theories of interference with synaptic transmission can be linked. It suggests that anaesthetics block ionic movement by affecting the cell membrane which in turn causes a fall in oxygen consumption and a rise in energy stores. Paton and Speden<sup>7</sup> support the hypothesis provided that the ionic movements considered are those concerned with the release and action

of chemical transmitters at the synapse. Mullins's theory<sup>9</sup> also supports an ionic block. The hypothesis is that the molecules of the inert gas occlude pores in the cell membrane, thereby preventing the passage of sodium during the initial phase of the generation of an action potential.

As a result of investigations on the action of 'n' alkyl alcohols, chloroform and ether on the film pressure or surface tension and the cation permeability of phospholipid model membranes, it was suggested that, on the contrary, "narcosis represents a transient reversible increase in membrane permeability to cation"<sup>10</sup>. The increased permeability is considered to be a result of the adsorption of narcotic agents into the cellular interfaces affecting the dielectric constant and changing the state of the membrane causing increased cation permeability.

An affinity of narcotic agents, including nitrous oxide, for interfacial films has been reported<sup>11</sup> and it was concluded that "inert gases at partial pressures, sufficient to bring about a standard effect in a biological system, act on a lipoprotein-water interface to cause a standard decrease of 0.39 dyne/cm in the interfacial tension".

Other experiments<sup>12</sup>, also with phospholipid model membranes, have established that increased pressures of nitrogen and a number of the noble gases also penetrate lipid membranes; the extent of the adsorption for the production of narcosis is in agreement with the rule of Clements and Wilson. Evidence was also obtained from these experiments that such penetration of lipid membranes may cause increased permeability of cations.

In the present experiments, the action of inert gases on sodium, potassium and chloride ions in the cerebral spinal fluid of cats exposed to narcotic and non-narcotic inert gases at raised pressures was investigated in order to determine the effect of such narcosis on ionic permeability *in vivo*. Under chloralose anaesthesia (55-60 mg/kg) a 3/8-in. hole was trephined in the skull of an adult cat and the dura reflected. A short, thin gauze wick from the hole led to a small plastic cup, in which was collected the cerebral spinal fluid. In addition, two stainless steel electrodes were screwed into the skull. One was placed over the frontal sinus as a reference and one a 0.5-in. lateral to the midline and a 0.25-in. posterior to the frontal-parietal suture. Natural auditory stimuli were produced by sharp raps on the side of the pressure chamber into which the cat was placed after the initial surgery. The resulting evoked potentials at the cortex were amplified and recorded on a Beckman 'Dynograph'.

For the first hour the animal remained at atmospheric pressure breathing air while auditory stimuli were presented every 3 min and the cerebral spinal fluid was collected. At the end of the hour, the full plastic cup was replaced and the chamber compressed to 11 absolute atm. with either 20/80 oxygen and nitrogen, oxygen and argon or oxygen and helium for a second hour. Again evoked potentials were presented and the cerebral spinal fluid was collected. After 1 h at the increased pressure, the cat was rapidly decompressed and the cup containing the cerebral spinal fluid was removed. In addition, control experiments were carried out where the second hour was also at atmospheric pressure.

Sodium and potassium ions in the cerebral spinal fluid were determined by flame photometry using dilutions of 1 in 20 for potassium ion and 1 in 500 for sodium ion against appropriate standards. Chloride ion was determined by the mercuric nitrate titration method of Schales and Schales<sup>13</sup>. The measurements were made by an individual who was unaware of the pressures or gases to which the cats had been subjected. The degree of narcosis produced in the cat by the inert gas was determined by measurement of the initial negative potential of the evoked response as described elsewhere<sup>14</sup>.

The mean electrolyte values in five cats during the first hour at atmospheric pressure are shown in Table I. The mean changes, during the second hour, while the cats were

exposed to various inert gases at increased pressures, are shown in Table 2. The control values are in agreement with existing data<sup>15</sup>. The only electrolytes to show a significant change from the controls were sodium and chloride ion in the cats exposed to either the nitrogen and oxygen or argon and oxygen mixture. These ions showed a significant depression in the cerebral spinal fluid. Potassium was not significantly affected throughout.

Table 1. MEAN VALUES FOR SODIUM, POTASSIUM AND CHLORIDE IONS IN CEREBRAL SPINAL FLUID OF FIVE CATS AT ATMOSPHERIC PRESSURE

	m.equiv.	S.E.M.
Sodium	177.8	± 4.5
Potassium	3.42	± 0.25
Chloride	147.6	± 4.6

As can be predicted from earlier work, narcosis was present only in cats exposed to either nitrogen or argon<sup>8,14,16</sup>. The evoked potentials were depressed by 18.6 per cent for nitrogen and 44.7 per cent for argon. In cats exposed to either helium or air at atmospheric pressure during the second hour there was no significant change in the evoked potentials. A similar electrolyte imbalance has been reported in guinea-pigs exposed to 6.6 absolute atm. oxygen during oxygen toxicity<sup>17</sup>. A significant increase in brain sodium ion occurred but potassium ion remained unchanged. In the present experiments the oxygen partial pressure at 2.2 absolute atm. is too low to be the cause of the electrolyte imbalance. Furthermore, that helium, with the same oxygen-partial pressure as the nitrogen and argon mixtures, did not affect the electrolytes further implicates the inert gas constituents as the cause.

Neurophysiological<sup>8</sup> and pharmacological investigations<sup>18</sup> have suggested that both oxygen and nitrogen or other inert gases can produce their toxic effects by similar mechanisms. In both conditions a hyperexcitability of the neurones develops, caused presumably by the influx of sodium ion. In the case of oxygen toxicity, however, the increased excitability eventually develops into oxygen convulsions whereas with the inert gases it develops into a depression of neurone activity and euphoria or anaesthesia.

The reasons for this difference remain to be elucidated, but it could be significant that as regards oxygen toxicity there is a reduction of the inhibitory transmitter  $\gamma$ -aminobutyric acid in the brain<sup>19</sup>.

Adrenalectomized animals similarly show increased brain excitability with an increase in brain sodium ion but no change in potassium ion<sup>20,21</sup>. The reason for this difference was resolved with the demonstration of a change in "exchangeable" potassium after adrenalectomy<sup>22</sup>. In normal animals only 80 per cent of brain potassium is "exchangeable" possibly because of membrane impermeability at either the cellular or intracellular level, or perhaps because potassium is chemically bound by brain lipids. After adrenalectomy, however, 100 per cent of the brain potassium becomes exchangeable.

It is therefore concluded that inert gas narcosis and anaesthesia are caused by the adsorption of the narcotic agent on cell membranes, which affects their permeability to cations and causes a reversible increase in intracellular ions. In addition there may be a modification of the distribution of intracellular potassium in brain neurones.

## BIOLOGY

### Finger-prints in Schizophrenia

THE investigation of epidermal ridges (dermatoglyphics) by prints of the fingers, palms and soles has found increasing application in genetic research. Dermatoglyphic investigations in schizophrenia<sup>1-7</sup> have been largely confined to the qualitative analysis of the finger-prints into pattern types. The results have been markedly inconsistent. The present investigation has attempted to resolve these inconsistencies by using a quantitative method of finger-print analysis, ridge counting. The sampling methods and diagnostic criteria, not described in the previous investigations, have been defined.

The 485 subjects were in-patients from four mental hospitals and all were of British ancestry. A one in three random sample was taken of patients, who had been continuously in hospital for more than 5 yr. They fulfilled the clinical criterion of being classifiable, according to Leonhard<sup>8</sup>, as chronic systematic schizophrenics. There were 155 males and 157 females in this chronic group. The acute patient group comprised seventy-seven males and ninety-six females, seen within 2 days of admission to hospital, and with K. Schneider's first rank symptoms of schizophrenia<sup>9</sup>. "Rolled" finger-prints were taken by an inkless method. The technique and rules for ridge

‡  $P 0.05$

counting<sup>10</sup>, the enumeration of the ridges between the triradius and core of the finger-print pattern, were followed. The sum of the ridge counts from all ten fingers is designated the total finger ridge-count. Its genetics and distribution have been extensively investigated in the normal British population<sup>11</sup>. This source provides the normal values for total finger ridge-counts cited here.

The means and standard deviations of the total finger ridge-counts, for the schizophrenic and normal samples, are given in Table 1. The measures of skewness ( $g_1$ ) and kurtosis ( $g_2$ ) of the distributions are also given, with their standard errors.

Table 1. DISTRIBUTION OF TOTAL FINGER RIDGE-COUNT IN SCHIZOPHRENIC AND NORMAL SAMPLES

Subjects	No.	Mean	S.D.	Skew ( $g_1$ )	Kurtosis ( $g_2$ )
Male					
Normal	825	144.98	51.08	-0.290 ± 0.085	-0.274 ± 0.171
Schizophrenic	232	132.24*	45.01	-0.152 ± 0.161	+0.112 ± 0.322
Female					
Normal	825	127.23	52.51	-0.230 ± 0.085	-0.451 ± 0.171
Schizophrenic	253	134.20	49.07	-0.217 ± 0.154	+0.110 ± 0.308

\* Significance of difference from normal mean  $P < 0.001$ .

The difference between the means of normal and schizophrenic males is highly significant ( $t = 3.695$ ,  $P < 0.001$ ), but the difference between females does not reach a significant level. There is a highly significant difference between the means of the normal males and females. This sex difference, which holds for most racial groups<sup>12</sup>, is abolished in the schizophrenic sample. Unlike the normal samples, the schizophrenic distributions are not platykurtic, nor is the negative skew significant.

These results are similar to the findings of the earlier investigators<sup>1-3</sup>, who found that the normal sex difference in the frequency of finger-print patterns was absent in their schizophrenic samples.

Analysis of variance of the schizophrenic total ridge-counts in terms of the diagnostic sub-categories, and acuteness, or chronicity, does not reveal any significant differences. The means of the diagnostic sub-categories, hebephrenic, catatonic, and paranoid schizophrenia, however, are noteworthy, because these results show a consistent pattern in both sexes. These means, with their standard errors, are given in Table 2.

Table 2. MEAN TOTAL FINGER RIDGE-COUNT IN SCHIZOPHRENIC SUB-CATEGORIES AND DIFFERENCE FROM NORMAL MEANS

Subjects	No.	Mean	Difference from normal	Significance of difference
Male*				
Normal	825	144.98 ± 1.78		
Hebephrenic	121	133.11 ± 4.56	-11.87	$P < 0.05$
Paranoid	85	136.24 ± 4.38	-8.74	N.S.
Catatonic	26	115.08 ± 9.98	-29.90	$P < 0.01$
Female†				
Normal	825	127.23 ± 1.78		
Hebephrenic	93	139.11 ± 4.91	+11.88	
Paranoid	127	134.80 ± 4.16	+7.57	
Catatonic	33	117.25 ± 8.42	-9.98	

\* Analysis of variance of means, differences significant,  $P < 0.01$ .

† Analysis of variance of means, differences not significant, therefore comparison with normal not made.

The means of paranoid and hebephrenic schizophrenics deviate towards the normal mean of the opposite sex. The deviations of the means of the hebephrenics, clinically the more severely affected, are greater. The means for catatonics of both sexes are lower than normal and are of the same order. These findings suggest that previous discrepant results could be a result of variation in the proportions of the three sub-categories in the total schizophrenic samples.

An explanation of the results of this investigation must be sought in genetic terms, for the total finger ridge-count is almost wholly genetically determined<sup>11</sup>. Current theories of schizophrenia, recently summarized<sup>13</sup>, favour a monogenic mode of inheritance, with environmental and other genetic factors modifying the expression and penetrance of the major gene. It is suggested that there is an association between the total finger ridge-count and

genes modifying the expression of the schizophrenic phenotype.

## Salivary Secretion in the Cattle Tick as a Means of Water Elimination

MANY observations have indicated that the engorgement of bloodsucking arthropods is accompanied by the elimination of excess water resulting in the concentration of the blood-meal. This water may be rapidly eliminated during or after feeding by the Malpighian tubules of mosquitoes<sup>1</sup>, tsetse flies<sup>2</sup> and bugs<sup>3</sup>, or by the coxal gland of argasid ticks<sup>4,5</sup>. This results in the ingested blood protein concentration being trebled, as in *Culex*<sup>6</sup>, or doubled as in the case of *Ixodes* and *Ornithodoros*<sup>5</sup> and *Argas*<sup>7</sup>, while the data of Kitaoaka<sup>8</sup> and Maddrell<sup>9</sup> also suggest a doubling for *Boophilus microplus* and *Rhodnius prolixus*.

During the final rapid engorgement of the cattle tick, *Boophilus microplus* (Canestrini), the weight of an adult female tick increases from 10 mg to more than 200 mg in less than 12 h, and recent work has confirmed that some concentration of the ingested blood occurs in this period. The degree of concentration is determined by the concentration of the haemoglobin of the host's blood (the relationship to the host haematocrit, although obvious, is less well marked because of variations in the erythrocyte haemoglobin levels). This was demonstrated by quantitative spectrophotometric analyses at 577 mμ of ingested oxyhaemoglobin from recently detached ticks. Fig. 1 shows that ticks from host animals with a low haemoglobin concentration had more than doubled the concentration of the ingested blood, whereas those from

Fig. 1. The relationship between the degree of concentration by the tick of its blood meal and the host blood haemoglobin concentration.

hosts with a high haemoglobin concentration had produced a lower degree of concentration.

It was established, by enclosing engorging ticks on the host in small polythene sheaths, that neither excretion through the Malpighian tubules nor transpiration across the cuticle was responsible for the water loss. In any case, the cuticular water loss from a fully engorged adult was shown to be no more than 10–15 mg for the time of the final 12 h period of engorgement. A possible mechanism suggested by Mr. J. D. Gregson (personal communication), however, was that the dilute clear oral secretion, which he had observed in *Dermacentor andersoni*<sup>10</sup>, was responsible for returning excess water to the host.

To test this hypothesis, eight ticks, 5–6 mm in length, which were already attached to a 16 month old calf (weight, 150 kg) were each injected at 16.00 h with 4.4  $\mu$ l. of 5 c./ml. (Code No. TRS. 1, Radiochemical Centre) tritiated water (sodium chloride added to 1 per cent). Any material which exuded from the puncture was absorbed with filter paper and immediately stored in water to enable the measurement of this loss of radioactivity from the tick. Under natural conditions these ticks would have engorged and detached by 09.00 h the next day. The ticks were therefore enclosed in open boxes with gauze coverings (to allow free exchange of gases and water vapour) stuck to the hide of the host. The following morning three ticks had engorged fully and detached, while the remainder were unchanged. Table 1 shows the recovery of 75 per cent of the injected radioactivity, of which 26 per cent was obtained from the calf, either from the urine or from a blood analysis extrapolated to an estimated total body water of 70 per cent. Tritium losses can be expected in expired water vapour, perspiration and faeces, which were not examined. It can also be seen that those ticks which did not engorge retained a considerable amount of the injected radioactivity. It is therefore concluded that during engorgement large amounts of water which have passed across the gut epithelium into the haemolymph are returned to the host in the salivary secretion of the tick. In the case of a tick engorging to a weight of 250 mg on a host with a haematocrit of 33 per cent it can be seen that this would be in excess of 200  $\mu$ l. of water, representing 60–70 per cent of the host blood water.

Table 1. PERCENTAGE RECOVERY OF 176 MC. TRITIATED WATER INJECTED INTO EIGHT TICKS (LIQUID SCINTILLATION COUNTING USING PPO IN ETHANOL-TOLUENE)

Source	Tritium (mc.)	Per cent of total injected
Five unengorged ticks	73.3	41.6
Three engorged ticks	3.8	2.2
Exudate from punctures	9.1	5.2
Host body water	23.9	13.6
Host urine	21.3	12.1
Total	131.4	74.7

Further confirmation of the water excretory function of the saliva has been provided by determinations of the chloride concentrations of oral secretion (collected by Gregson's technique<sup>10</sup>), haemolymph and whole engorged ticks.

The chloride levels of the oral secretion and haemolymph were found to be approximately equal at 110–130 m.equiv./l. Haemolymph chloride concentration will be maintained by Donnan equilibrium at a higher level than that of the gut contents. In consequence, the secretion of isotonic chloride in the saliva will result in the progressive elimination of chloride from the tick and the avoidance of the osmotic imbalance which would result from the loss of water alone.

A variety of other substances of probable host origin such as urea and histamine are also found in the oral secretion and it seems likely that they, too, are being eliminated by this method.

Thus it would seem that in *B. microplus* and probably other Ixodidae the blood meal is concentrated, and electrolytic and osmotic imbalance avoided by a remark-

able adaptation of the salivary secretion. The effect of host haemoglobin levels on the degree of concentration of the blood ingested by the cattle tick is interesting and may be significant in the feeding of other blood-sucking arthropods. The general similarity in the proportion of water eliminated from the blood meals of different blood-feeders, despite their different metabolic and ecological requirements, may be significant also. It perhaps indicates that this phenomenon is controlled by physical factors which limit the ability of water to leave the blood mass and cross the gut epithelium.

### Differences in Light Reactions of Larvae of the Armyworm, *Leucania separata* Walker, in relation to their Phase Status

THE coloration, rate of development and behaviour of the larvae of the armyworm, *Leucania separata* Walker, differ when the larvae are subjected to different degrees of crowding during development. Active black larvae appear in crowded conditions and develop more rapidly, feed more voraciously, and tolerate starvation and less palatable food-plants better than the sluggish pale larvae that appear in uncrowded conditions. This phenomenon has much in common with phase polymorphism in locusts<sup>1</sup>.

The armyworm is normally a nocturnal feeder in the latter half of its larval stage, but hordes of larvae often feed and move by day as well. We have investigated whether this change in daily rhythmic activity is related to internal changes associated with phase transformation.

Pale larvae reared in isolation, and black larvae reared in crowds of twenty individuals/container, were used. Tests were carried out in the dark at 30° C and relative humidity about 80 per cent. Each larva tested was released 70 cm from a 5 W lamp on a 90 cm x 60 cm black board. A considerable number of mid- and late-instar larvae travelled towards the lamp. The time required for each larva to crawl from the starting point to the line on which the lamp was placed was recorded. Table 1 shows that black larvae from crowded cultures travelled more rapidly to the line than the pale larvae reared in isolation. Several larvae, especially pale ones, never reached the goal line; they either moved in another direction or remained motionless. This difference in reaction became clearer as the larvae developed (Table 1, instars 3, 4 and 5).

The light reaction of larvae of the fifth and sixth instars was investigated. The larvae made six kinds of tracks (Fig. 1). Tracks A and B were regarded as photopositive reactions, although some larvae changed their route after

Table 1. TIME REQUIRED BY PALE AND BLACK LARVAE OF *L. separata* TO TRAVEL TO A POINT SOURCE OF DIM LIGHT

† Letters refer to types of tracks illustrated in Fig. 1. A, B, and C are photopositive, D probably and E always are photonegative, and F indicates virtual immobility.

reaching the vicinity of the light source and then passed by it (B). Some photopositive individuals circled for a time on their way to the light or compassed around it (C). Some larvae left the side of the arena (D), and many of these showed photonegative behaviour when placed near the lamp. Track E shows a more typical, initially photonegative reaction, and track F shows the larvae essentially motionless in the arena, with or without a brief period of movement.

Table 2 shows that black larvae were consistently more active and more photopositive than pale larvae. In the sixth instar, however, the percentage of black larvae that took track C increased, and by the third day in that instar the percentage that could be termed truly photopositive had decreased considerably. This change could be associated with the onset of the period of prepupal travel. On the other hand, the percentages of pale larvae that remained immobile or reacted photonegatively were large in both instars.

The response of black larvae to light is not always a simple photopositive reaction, but they do respond to the position of a point source of dim light while they move. On the other hand, those pale larvae that were not photonegative seem to be disorientated. Both types of larvae were repelled by a brighter light, so that daytime activity of the larvae in outbreak conditions could be related to some other factor(s), such as starvation. This difference in response to light indicates, however, that there is some internal difference between pale and black larvae and that it may be an underlying cause of the differential daily rhythms of larvae at low and high population densities.

The greater activity of black larvae and their greater ability to orientate to a light source suggest that they have better developed exploratory behaviour than pale larvae. This seems compatible with Kennedy's hypothesis concerning locust phases<sup>2</sup>, in the sense that black larvae (corresponding to ph. *gregaria* in locusts) are more specialized in a "sensorimotor" direction.

It is also interesting that the differences in the efficiency of orientation of both the high-density (black) and the low-density (pale) phases of the larvae (see tracks A and B, track F and possibly track C, dotted, in Fig. 1) are similar to those observed between the active and sluggish larvae of species of *Malacosoma*<sup>3,4</sup> in which maternal

nutrition is partly responsible for the determination of types of the progeny larvae<sup>5</sup>. Table 2 illustrates this resemblance. This indicates that in *L. separata*, and possibly in some other species, the behavioural differences as seen in *Malacosoma* can be brought about by different degrees of crowding during larval development. At the same time, the differences in efficiency of orientation within the larvae of each phase suggest that some other factor, such as nutritional conditions or the degree of crowding in the parent generation or a genetic factor, could also be involved in the partitioning of larvae into a series of behavioural types.

I thank Professor Syunro Utida for his interest and encouragement, and Dr. W. G. Wellington for his criticism and suggestions.

## Fallopian Tube and Early Cleavage in the Mouse

TECHNIQUES have been perfected for the culture *in vitro* of late two cell mouse ova into blastocysts in simple chemically defined conditions<sup>1,2</sup>. Attempts to obtain development from earlier stages have failed, unless the ova were cultured in organ cultures of the fallopian tube<sup>3,4</sup>. These results suggested that the fallopian tube provides some critical contribution necessary for the development of the mouse zygote into the late two cell stage. Nevertheless, it has been a common experience that when the mouse zygote is cultivated independently of the fallopian tube a few cleave to the two cell stage and then cease development<sup>5</sup>. It has now been shown<sup>6</sup>, however, that a high percentage of zygotes cleave to two cell stages and then cease development when cultured in Waymouth<sup>7</sup> medium supplemented with ATP, deoxynucleosides and a feeder layer of irradiated HeLa cells. These experiments suggest that the initial development of the mouse zygote is dependent on a supply of exogenous factors, additional to those required by later stages.

This report presents evidence that zygotes can develop *in vitro* into two cell ova, independently of the fallopian tube, in the same simple culture conditions sufficient to support the development of late two cell ova, and, in addition, that the two cell ova produced in this way are viable and capable of further development only if they are exposed to the environment of the fallopian tube between the first and second cleavage divisions.

Fertilized one cell ova were obtained from the ampullary regions of fallopian tubes of superovulated 7-8 week old random bred Swiss mice on the morning the vaginal plugs were found. The mice were superovulated by an intraperitoneal injection of 10 IU of pregnant mare serum gonadotrophin ('Gestyl', Organon) followed 48 h later by an intraperitoneal injection of 10 IU of human chorionic gonadotrophin ('Pregnyl', Organon). The cumulus cells were removed with hyaluronidase (300 U/ml. of Dulbecco's phosphate buffered salt solution<sup>8</sup> (pH 7.2) to which 1 mg/ml. of polyvinylpyrrolidone was added). The ova were then washed in several changes of a pyruvate : lactate medium<sup>9</sup>, and finally set up in cultures according to the previously described method of Brinster<sup>1</sup>. Twenty-four hours later the number of ova which had undergone the

\* One cell ova collected approximately 24 h after injection of human chorionic gonadotrophin.

first cleavage division was noted. In five experiments (Table 1) 60 per cent to 70 per cent of the uncleaved ova proceeded through the first cleavage division. This yield was consistent between all experiments, and is of the same order as that observed by Cole and Paul<sup>6</sup>.

In another two experiments one cell ova were cultivated simultaneously with and without an energy source in the medium. The pooled results (Table 2) demonstrate unequivocally that development through the first cleavage division is dependent on an exogenous source of energy.

Two cell ova from the first three experiments (Table 1) were transferred into organ cultures of the ampullary regions of fallopian tubes, which were obtained from 7-8 week old random bred Swiss mice in early metoestrus I. The oestrous cycles were synchronized by the intra-peritoneal injection of 5 IU of pregnant mare serum gonadotrophin ('Gestyl', Organon) and 5 IU of human chorionic gonadotrophin ('Pregnyl', Organon) after 48 h. Twenty to twenty-two hours after the second injection the fallopian tubes were removed, carefully uncoiled and transected in the approximate region of the ampullary isthmal junction. The unfertilized ova within the cumulus mass were then flushed out of the ampulla. This ampullary region was explanted on Ham F10 medium<sup>9</sup> supplemented with 100 U/ml. of penicillin G (potassium salt) and 50 µg/ml. of streptomycin sulphate, which had previously been found to be the best medium for maintaining the fallopian tubes in organ culture (unpublished work of Whittingham). Chen's method<sup>10</sup> of organ culture was used. Each ampulla was cultivated on a raft of tea-bag paper floating on 0.5 ml. of medium. The medium was renewed after 48 h by transferring the tea-bag paper plus ampulla to a fresh culture chamber. The cultures were incubated at 37° C in a desiccating cabinet through which humidified 5 per cent carbon dioxide in air flowed continuously. Twelve ova were transferred to each ampulla approximately 1 h after the ampullae were placed in organ culture and left for 72 h. The ampullae were then flushed and the number of blastocysts and morulae developing from these two cell ova counted (Table 3). The results show clearly that the two cell ova produced from zygotes *in vitro* are capable of further development when transferred to the ampulla of the fallopian tube.

The viability of blastocysts obtained by the procedures just described was examined by transferring them into uterine foster-mothers. Albino Swiss blastocysts were

Table 3. DEVELOPMENT OF BLASTOCYSTS FROM CULTURED TWO CELL OVA TRANSFERRED INTO EXPLANTED AMPULLAE FOR 72 H

Experiment	No. of two cell ova transferred	No. cleaved*	No. of morulae	No. of blastocysts	Percentage of blastocysts
1	60	33	2	27	45.00
2	60	38	5	21	35.00
3	120	65	11	40	33.3
Total	240	136	18	88	36.7

\* Number of two cell ova which have cleaved at least once; this includes those ova which have developed to morulae and blastocysts. Degenerated or fragmented ova were discarded.

transferred into pseudopregnant nulliparous *F*<sub>1</sub> hybrids (*C3H* female × *DBA* male) 2.5 days after ovulation, using methods already described<sup>11</sup>. Seven blastocysts were transferred into the left uterine horn of each of thirteen recipients. On the seventeenth day the uterine contents were examined and four were found to be pregnant. Altogether six apparently normal fetuses and five resorption sites were found. These results are comparable with those obtained by the transfer of blastocysts cultured from the late two cell stage. Thus embryos which have undergone their first division *in vitro* independently of the fallopian tube are capable of development into normal fetuses.<sup>6</sup>

These results demonstrate that the development of the mouse zygote to the two cell stage *in vitro* is dependent on an exogenous source of energy, as are the later stages leading to the development of the blastocyst. Presumably, in natural conditions this energy supply is provided by the mother. The notion<sup>12</sup> that the cytoplasm of mammalian ova contains sufficient nutrients to sustain zygotic development cannot be upheld. Whether the development of the two cell ovum requires an exogenous nitrogen source, as do later cleavage stages<sup>13</sup>, has still to be determined. Nevertheless, the results show that this early stage of development does not require any factors additional to those of late two cell stage. The results also show that the environment of the fallopian tube is only required to promote development in the earlier phase of the period between first and second cleavage. The nature of the contribution of the fallopian tube is unknown.

### Dose Rate Effect of Radiation on Spermatogonia of the Silkworm

IN mice the mutation rate in irradiated spermatogonia is less at low dose rates (0.009 r./min) than at high dose rates (90 r./min and more)<sup>1,2</sup>. Tazima *et al.*<sup>3</sup> have observed that the mutation frequency for chronic irradiation is higher than that for acute irradiation when the silkworms are irradiated about 7 days after hatching. To explain such a peculiar dose rate effect, various hypotheses<sup>3,4</sup> have been proposed. In this communication, the effect of dose rate on death and repopulation of spermatogonia is cytologically analysed with particular reference to the possibility of selective elimination of the cells after

exposure to different dose rates of radiation. The spermatogonia of the silkworm are readily killed by acute irradiation<sup>5,6</sup>.

For the chronic irradiation, cobalt-60  $\gamma$ -rays were administered continuously for 122 h from 5 to 10 days post hatching, with a total dose of 1,000 r. (0.136 r./min). The acute irradiation was carried out 7 days after hatching with a dose rate of 200 r./min for 5 min. Every 24 h after the initiation of chronic irradiation or the completion of acute irradiation, the testes of the larvae in each experimental group were fixed with PFA-3 fixative, embedded in paraffin, and sections 7  $\mu$  thick were stained with Mayer's acid haemalum. Both pycnotic and non-pycnotic spermatogenic cells in the testes were scored on serial sections of the specimens under the microscope. As indicated in Fig. 1, in the group which received chronic irradiation pycnotic figures of the spermatogonia began to appear 24 h after the initiation of exposure and increased with time, showing a maximum at 72 h. Thereafter, pycnosis decreased and disappeared almost completely before the exposure was terminated. In the testes which were acutely irradiated, however, pycnotic spermatogonia had already reached a maximum level 48 h after irradiation. Afterwards they decreased rapidly. On the other hand, the number of non-pycnotic spermatogenic cells (surviving or newly formed cells) was reduced remarkably after both acute and chronic irradiations. In both cases, however, the apical cells, primordial germ cells and some very young spermatogonia were left intact. The number of such surviving cells remained constant for a while, indicating inhibition of cell division. After several days spermatogonia began to regenerate steadily at both dose rates. The cells then increased in number rapidly and reached the control level by the end of the fourth instar. Throughout the experiment, it can be said that the extent of spermatogonial death and the number of surviving or

newly formed cells is approximately similar at the two very different dose rates used in this experiment, except for the initial cell degeneration after the exposures.

We conclude that cell selection is not involved in the dose rate effect on mutation frequency in the spermatogonia of the silkworm. The same conclusion was reached for the dose rate effect in mouse spermatogonia<sup>3,7-9</sup>. It should, however, be noted that in the silkworm the surviving spermatogonia remain in a state of arrest for several days after irradiation. Possibly, the surviving cells are arrested in a stage of development in which they are particularly sensitive to mutation by radiation. In this respect Sado<sup>10</sup>, using the uptake of <sup>3</sup>H-thymidine, reported that surviving cells were accumulated at G2 of the division cycle after irradiation. More detailed experiments, however, are necessary before any firm conclusion can be drawn.

We thank Dr. Y. Tazima, National Institute of Genetics, Mishima, for his help.

## Culture of Tomato Callus Tissue

REPORTS on the growth and division of plant cells in culture media have had various objectives: to establish the totipotency of the diploid cell<sup>1-4</sup>; to grow the whole plant from an isolated single cell, in a defined medium without neighbouring cells or tissue, a goal very recently achieved<sup>5,6</sup>; to use a defined medium, as distinct from a conditioned medium, that is a medium on which cells have previously been grown<sup>5-7</sup>; to explore the nature and mechanism of factors inherent in coconut milk<sup>1,8,9</sup> or pea<sup>10</sup> which promote cell division.

In our case, the purpose is to extend the time available for investigation of changes in pigmentation in the fruit of the ripening tomato, which can be short. This is especially true of fruit containing the gene *lutescent* (*l*). On one day it may appear a normal ripe yellow; two days later it may have turned red. Chlorophyll synthesis has been noted in masses of endive callus<sup>4</sup>. Accepting the view that the cell is totipotent, we believe that it should be possible, with masses of callus, to investigate the nutritional requirements and physical environment for carotenoid synthesis in tomato fruit.

Attention is drawn to three points of interest: an unusually rapid growth rate; the effect of pea extract, as contrasted with that of kinetin; differences in genotypes. With the fastest growing strain, a 200-fold increase in 2 weeks has been achieved, so that with four or five pieces, each about 30–40 mg in weight, sub-cultured on a nutrient medium containing agar, 20–30 g of cells can be obtained as needed (Fig. 1). We tested first a modification of White basal medium<sup>11</sup> with 2 per cent sucrose and vitamin and trace element supplements, and the following additions: casamino-acid (2 g), *L*-tryptophan (0.02 g), kinetin (80  $\mu$ g), indolyl-3-acetic acid (0.01 g) and 2,4-dichlorophenoxyacetic acid (3 mg)/l. As shown in Table 1, there was little or no growth.

Table 1. FRESH WEIGHT OF CALLUS, IN GRAMS, 14 DAYS, 28° C

Genotype		Medium			
		Basal	Basal + pea extract		
		1	1*	2	3
Red	<i>r<sup>+</sup>t<sup>+</sup></i>	0.083	1.09	1.18	0.56
Red lutescent	<i>r<sup>+</sup>t<sup>+</sup>l</i>	0.056	0.80	0.94	—
Yellow	<i>rt<sup>+</sup></i>	0.094	1.42	1.41	—
Tangerine	<i>rt<sup>+</sup></i>	0.044	0.35	0.46	—
Red ghost	<i>r<sup>+</sup>t<sup>+</sup>gh</i>	0.019	0.16	0.42	—
Tangerine ghost	<i>r<sup>+</sup>t<sup>+</sup>gh</i>	0.028	0.11	0.18	0.17
Yellow ghost	<i>rt<sup>+</sup>gh</i>	0.045	1.13	2.69	5.64

\* Values for run No. 1 are the averages of five samples each; for runs 2 and 3, four samples; the inoculum varies from 0.02 to 0.03 g.

With pea extract, however, results were dramatically different. The medium was prepared as follows: 250 g of frozen peas from the market were blended in 1 l. of distilled water and autoclaved for 10 min at 120° C and centrifuged. White solution, with 2 per cent sucrose, was then added to the supernatant. To ensure a clear solution (for liquid media) it was passed through a thin layer of 'Hyflo supercel', and the vitamins and growth factors were then added. The medium was then autoclaved at 120° C for 12 min, with the addition of agar (0.8 per cent) when a solid medium was desired.

Other additions to the medium, singly or in combination, included yeast RNA alkaline hydrolysate, cholesterol, and thiourea, at concentrations of 200 µg (based on the weight of unhydrolysed yeast RNA), 10 µg and 10 µg/l. respectively. No unequivocal effect was noted on growth, although thiourea kept the callus mass light in colour.

The starting material consisted of about 1 mg of hypocotyl tissue taken from seed which had been immersed for 30 min in 1 per cent sodium hypochlorite and washed three times in sterile water. The pieces of hypocotyl were placed on slants and changed to callus in 1–2 weeks. After several transfers to fresh medium, growth rates increased. The following tissue cultures were grown: red *r<sup>+</sup>t<sup>+</sup>*, yellow *rt<sup>+</sup>*, tangerine *rt<sup>+</sup>*, lutescent *r<sup>+</sup>t<sup>+</sup>l*, red ghost *r<sup>+</sup>t<sup>+</sup>gh*, tangerine ghost *r<sup>+</sup>t<sup>+</sup>gh*, and yellow ghost *rt<sup>+</sup>gh*.

Data in Table 1 permit comparison between the basal medium alone and the medium supplemented with pea extract. Results for the latter are averaged, and include combinations of thiourea, cholesterol and the RNA hydrolysate. Probably the most critical requirement is that the inoculum be in its most active phase. This seems to be the best explanation for the very rapid development for yellow ghost, *rt<sup>+</sup>gh*, as a result of numerous transfers; by contrast red, *r<sup>+</sup>t<sup>+</sup>*, run three, may have had unintentionally a less active inoculum.

Cultures involving *t*, whether alone or in conjunction with *gh*, have so far invariably shown slow growth. Cells

were characteristically spherical in shape, about 40µ (red) and about 100µ (yellow and tangerine) in diameter, but some of the latter were elongated, about 130 × 50µ. The cultures are not initially of isogenic stock, so that such differences cannot be ascribed to effects of the known gene differences. These differences in cell size are not reflected in dry matter content. After 14 days, dry matter was uniformly between 3.7 per cent and 3.9 per cent. It rose to between 5 per cent and 6 per cent for 1-month-old cultures. These figures may be compared with values between 4 per cent and 5 per cent<sup>10</sup> calculated at the period of the maximum growth rate for tobacco callus.

Nitrogen content was determined by micro Dumas and micro Kjeldahl procedures. Again no significant differences between strains were observed. By micro Dumas, the average value for four strains was 0.2 per cent nitrogen, that is about 5 per cent on a dry weight basis. Kjeldahl nitrogen was slightly lower, three samples yielding values of 3.61 per cent, 3.78 per cent and 3.70 per cent on the dry weight basis.

Total nucleic acid was run on the fast-growing *rt<sup>+</sup>gh* by the method of Ogur and Rosen<sup>12</sup>. The nucleic acid spectrum was identical in shape, from 230 mµ to 280 mµ, with that reported for carrot explants<sup>1</sup>. Based on an average E value of 25 for a concentration of 1 mg/ml., the total nucleic acid content was almost exactly 1 per cent of the dry weight. Comparisons are difficult, because for bacteria a much higher content, about 10 per cent, is not unusual, and the analysis may well have been made, at 14 days, past the peak (see ref. 1).

It can be emphasized that a rapid growth rate requires that the inoculum itself be highly active, and that the rate can be enhanced by repeated transfers.

The U.S. National Science Foundation supported this work with a grant. We thank Mr. J. J. Jen for carrying out the nitrogen determinations.

### Changes in the Shoot Apex during the Early Development of the Fern *Marsilea vestita*

*Marsilea* is an aquatic fern which can be grown in sterile culture and which passes through a juvenile phase before reaching adulthood. It is therefore an ideal plant to use in examining the events at the shoot apex which lead up to the production of juvenile and, later, adult leaves. Allsopp<sup>1</sup> has suggested that in *Marsilea* a small apical meristem initiates primordia with a relatively limited capacity for development, and Cutter<sup>2</sup> states in her review: "It is thus held that there is an important correlation between the size of the shoot apex and the extent of development of the leaf primordia to which it gives rise, leaf primordia formed on a large apex being capable

Fig. 1. Twenty-eight-day culture of tomato callus (yellow, *rt<sup>+</sup>*).

of developing into adult leaves, whereas those formed on a small apex are considered to have only a limited capacity for growth and development. Apical regions of well-nourished sporelings with adult leaves are seen by inspection to be larger than those of less-well-developed sporelings with juvenile leaves, but no detailed study of changes in size of the apex in *Marsilea* has yet been undertaken". The object of this communication is to find out whether there is any correlation between the size of the shoot apex and the production of juvenile or adult leaves.

Sterile sporelings of *M. vestita* Hook. and Grev. were obtained from surface-sterilized sporocarps and grown in sterile White nutrient fortified with 3 per cent sucrose and left under continuous fluorescent light (150 ft.-candles) or placed in darkness. Twenty-five plants were sampled at seven different times and their apices were fixed, sectioned at  $7\mu$ , and stained<sup>3</sup> to yield median longitudinal apical sections. These were drawn with the aid of a camera lucida and the apex was delineated by an imaginary base line drawn immediately above any recognizable leaf primordium at  $90^\circ$  to the axis of the shoot (Fig. 1). The parameters measured by means of a planimeter from the drawings of the apices were: the area, and the total cell number of each section. Each point on the graph in Fig. 2 represents ten median sections.

Juvenile leaves of *Marsilea* have unifid, bifid or trifid laminae, and the first leaf to appear which has a quadrifid

Fig. 1. Drawings of shoot apices of *Marsilea vestita*: (A) six day old plant grown in the light; (B) 30 day old plant grown in the light; (C) 30 day old plant grown in the dark. The large triangular apical cell is drawn at the top of the apex of the shoot. The apical cell to the left in A and B belongs to a group of cells which are about to become a leaf primordium.

Fig. 2. Graph of sectional area (—) and cell number (---) of shoot apex of *Marsilea*. Standard errors indicated by horizontal lines.

Table 1. EFFECT OF DARKNESS ON SHOOT APEX OF 6 DAY OLD *Marsilea* PLANTS

Treatment	Sectional area shoot apex $\times 10^4 \mu^2$	Cell number in section of shoot apex
None	1.31 (0.14)	10.90 (0.15)
Darkness (24 days)	2.15 (0.34)	11.60 (0.61)
Light (24 days)	3.46 (0.25)	22.70 (0.90)

Standard error of each mean in parentheses.

lamina is arbitrarily designated as the first adult leaf<sup>4</sup>. At 17–20 days the plant ceases to produce juvenile leaves and begins to produce adult leaves. This transition to adulthood can be correlated with a change in the size of the apex, for all parameters increased gradually (Fig. 2). There is a plateau in the graph of the area of the apex just before adult leaves begin to appear. Most of the increase in size of the apex was the result of an increase in cell division, because cell number increased considerably with age (Fig. 2). From Sossountzov's cytological examination of the shoot apex of *Marsilea* we know that the majority of cell divisions occur in those areas below the apical cell and prismatic layers. These areas correspond to "sub-distal" and "organogenic" regions in fern apices<sup>5</sup>. It is evident here that adult leaves were produced on an apex of increasing size and that further increase in size of the apex occurred while further adult leaves were being produced. This raised the question of whether or not adult leaves can be produced on a small apex.

It has been shown<sup>6</sup> that the shoot apex of *Marsilea* is smaller in plants grown in darkness (Fig. 1). Average measurements of seven median longitudinal sections from plants grown in darkness (Table 1) show that etiolation caused a marked reduction in the area and cell number of the shoot apex. Etiolation does not affect the diameter of the apical cell or its nucleus as shown by actual measurement with an ocular micrometer. If *Marsilea* is supplied with a carbon source it will grow and produce adult leaves in total darkness (although the leaves do not expand as in plants grown in the light). This production of adult leaves occurred when the dark-grown plants possessed shoot apices which were as small as the apices of 12 day-old juvenile plants. Thus, if there is a correlation between the size of the shoot apex and the production of adult leaves, it was not evident here.

## AGRICULTURE

### Variation in Concentration and Composition of Toxic Alkaloids among Strains of *Phalaris tuberosa* L.

In recent years there has been an increasing number of deaths in flocks of sheep which have grazed pastures dominated by the Australian commercial strain of phalaris (*Phalaris tuberosa* L.)<sup>1</sup>. There were many cases of acute phalaris poisoning on the tablelands of New South Wales in 1965. In some flocks losses were as high as 20 per cent.

Several dimethyltryptamine alkaloids, which are known to occur in phalaris herbage<sup>2</sup>, have been implicated as the toxic substances<sup>3</sup>. The syndrome of nervous and heart malfunctions induced by injecting these alkaloids

closely resembles that observed in cases of field poisoning.

To determine whether strains with low concentrations of these alkaloids occur in nature, ecotypes from the entire geographic range of the species in the Mediterranean region have been assayed. These ecotypes are referred to by their Commonwealth Plant Introduction numbers. Four breeding populations and the Australian commercial strain were also assayed. Twenty-two strains were grown with little nutrient or moisture stress in a controlled environment chamber at day/night temperatures of 21°C/16°C and 8-h day length. Herbage was also collected from swards of six of these strains grown in the field near Canberra. At the time of collection in mid-winter, nearby stands of the commercial strain were highly toxic. At each harvest, the plants were cut approximately 0.5 in. above the level of the root medium. The fresh herbage was frozen rapidly and stored in vacuum flasks with dry ice. The alkaloids were extracted in 0.1 normal hydrochloric acid and purified by solvent partitioning. After separation by paper chromatography, the alkaloids were assayed colorimetrically. The extraction and assay procedures used were those of Bogdanski *et al.*<sup>4</sup> and of Weissbach *et al.*<sup>5</sup>, respectively, as modified by Gallagher, Koch and Chia (personal communication).

The accuracy of the chromatographic and colorimetric techniques was high, the variation between duplicate samples being about 1 mg of alkaloid/100 g of dry matter. Large sampling errors occurred earlier in the overall procedure, probably at the time of sampling the herbage from the swards or pots.

There was a twenty-fold variation in the concentration of the dimethyltryptamine alkaloids among the twenty-two strains (Tables 1 and 2). The strain means appear to be continuously distributed. In the field samples the total alkaloid concentration was higher in the commercial strain than in any of the other five strains. Among the wider range of strains grown in the controlled environment, several were found with high alkaloid concentrations. On the other hand, a number of strains were considerably lower in alkaloid concentration than was the commercial strain.

Three compounds were common to all strains, *N,N*-dimethyltryptamine, 5-methoxy-*N,N*-dimethyltryptamine and 5-hydroxy-*N,N*-dimethyltryptamine (bufotenine).

		Least significant differences (5 per cent)				(0.37)	(0.40)

Concentrations are in mg/100 g of dry matter.

\* Values for concentrations of total alkaloids ( $\bar{x}$ ) were transformed to  $\log_{10} \bar{x}$  for statistical analysis.

† Values for concentrations of dimethyltryptamine ( $y$ ) were transformed to  $1 + \log_{10} y$  for statistical analysis.

Traces of unidentified related compounds also occurred in some strains. The concentration of bufotenine was small in all strains, and there were marked differences between the strains in the proportions of *N,N*-dimethyltryptamine and 5-methoxy-*N,N*-dimethyltryptamine (Tables 1 and 2).

The ranking of six strains with respect to total alkaloid concentration was not consistent when these were grown in the field and in a controlled environment chamber ( $r=0.20$ ,  $P \gg 5$  per cent) (Table 1). The total alkaloid concentration in the commercial strain is known to be affected markedly by many environmental factors, particularly soil nitrogen level and light intensity<sup>6</sup>. The differences which existed between the field and the controlled environments had a consistent effect on the concentration of *N,N*-dimethyltryptamine in the six strains ( $r=0.94$ ,  $P < 1$  per cent), but their effects on the concentration of 5-methoxy-*N,N*-dimethyltryptamine varied considerably among these strains ( $r=0.78$ ,  $P > 5$  per cent). Despite this genotype-environment interaction, the total alkaloid concentration in one strain was much lower than in the commercial strain in both environments.

Neither the concentration nor the composition of the alkaloids appears to be related to the area of origin or to any agronomic character of the strains. It would therefore seem feasible to breed agronomically acceptable strains of phalaris which have low concentrations either of any particular dimethyltryptamine alkaloid or of all such compounds. The requisite investigation of the inheritance of the alkaloid differences is in progress.

## PSYCHOLOGY

### Positive and Negative Reinforcement from Intracranial Stimulation in Pigeons

SINCE the discovery of reinforcement by intracranial stimulation in rats<sup>1</sup>, neural systems of reward and punishment have been investigated in a number of mammalian species (for example, in monkeys, cats, dogs, goats, dolphins, and man<sup>2-7</sup>), but only one study<sup>8</sup> using a non-mammalian species (goldfish) has been published. At least one theoretical account of self-stimulation<sup>9</sup> relies on the notion that it depends on the simultaneous excitation of two functionally distinct, but anatomically contiguous, neuronal systems. Comparative studies might be expected to throw light on this hypothesis, because the functional systems involved need not necessarily be contiguous in all species. From this point of view, the

restriction of previous investigations to the class of mammals is regrettable, because the areas that appear to be primarily involved in reward and punishment, the limbic system and the hypothalamus, have developed structurally very little through the evolution of mammals<sup>10</sup>.

The development of the avian forebrain from reptilian structures has followed a very different course from that taken by the mammals, the most striking differences being the absence, in birds, of any distinct neo-cortical layering and the greater development of the striatal regions<sup>11</sup>. Despite these anatomical contrasts, few studies of the functions of the avian forebrain areas, and none of the reward value of intracranial stimulation, have been published.

A pair of bipolar twisted silver electrodes was implanted in the telencephalon of each of twenty-three adult domestic pigeons (*Columba livia*) while they were anaesthetized with 'Nembutal' supplemented with ether, and held in a modified rat stereotaxic apparatus, using a holder, adapted from Gogan<sup>12</sup>, that held the lachrymal ducts at the same height as the ears. Following tests, animals were perfused with 10 per cent formol saline, and serial sections in the plane of the electrode tract were cut at 15  $\mu$ . The slides were stained with haematoxylin and eosin, and those in the proximity of the tip silver-stained by the Glees method<sup>13</sup>.

The method used to evaluate the reward value of intracranial stimulation is similar to that used by Wilkinson and Peele<sup>3</sup> in their study on cats, and is made necessary by the difficulty of establishing a satisfactory operant level of any response that can be used to operate a micro-switch. The technique adopted ensures a large number of pairings of the operant response (pecking a key) with delivery of intracranial stimulation. Subjects were deprived of food, and trained to obtain wheat rewards in a Skinner box on a fixed ratio schedule of one reward to ten responses. They were then given a series of acquisition and extinction sessions until stable, rapid extinction was achieved after an acquisition period of a fixed length (200 responses, yielding twenty food rewards). A 0.4 sec train of intracranial stimulation was then introduced for every response throughout a session, the current being raised in 10  $\mu$ amp steps from 10 to 60  $\mu$ amp, and thereafter in 20  $\mu$ amp steps up to 160  $\mu$ amp. It is reasoned that aversive stimulation should slow down the rate of responding for food reward, and that rewarding stimulation should sustain responding in the absence of food reward.

Fifteen subjects met the reward criterion (more than 50 responses in each of two successive extinction periods), four met the punishment criterion (failure to complete the 200 response food-rewarded acquisition period within 10 min), and four, meeting neither criterion, were classified as neutral. Subjects meeting the reward criterion were given eight sessions at threshold current strength (thresholds ranged from 10 to 120  $\mu$ amp); mean rates of response in excess of 3,000/h were recorded during 20 min periods following cessation of food delivery. Further analysis of the performances of these subjects revealed that, in some cases, the rate of responding for food reward was lowered by intracranial stimulation at the same current levels that sustained extinction responding, although not to such an extent that the punishment criterion was met. Subjects in which this phenomenon was demonstrated were classified as ambivalent, this behaviour being interpreted as due to the simultaneous activation of rewarding and punishing pathways.

Histological analysis of the sites of the electrode tips showed: (a) of five placements in the hyperstriatum, two were rewarding, one ambivalent, one punishing, and one neutral; (b) four of seven neostriatal placements were rewarding, one was ambivalent, and two neutral; (c) three palaeostriatal electrodes were rewarding and two were ambivalent; (d) the single archistriatal placement was neutral; (e) three septal electrodes were punishing

Fig. 1. Frontal section through pigeon brain, at the level of the anterior commissure. AC, Anterior commissure; As, archistriatum; Es, actostriatum; HsA, hyperstriatum accessorium; HsD, hyperstriatum dorsale; HsV, hyperstriatum ventrale; Ht, hypothalamus; LFB, lateral forebrain bundle; MFB, medial forebrain bundle; NR, nucleus rotundus; Ns, neostriatum; Ps, palaeostriatum; SA, septal area. ●, "Pure" reward; ▲, ambivalent; ■, aversive.

and two were ambivalent. Fig. 1 is a diagram showing the sites of all the electrodes classified as rewarding or punishing, distinguishing ambivalent responders from "pure" reward subjects; for the sake of clarity, all loci are shown at the same rostro-caudal level. From Fig. 1 it can be seen that, in general, placements affecting the lateral forebrain bundle and palaeostriatum are rewarding, those influencing the medial forebrain bundle and septal area are aversive, and electrodes capable of influencing both structures are ambivalent; in particular, it can be seen that the four ambivalent electrodes in the palaeostriatum and septal area fall in areas where the two structures are in close proximity. Because the septal area and medial forebrain bundle of mammals are generally accepted as part of the reward system in mammals, a surprising contrast between avian and mammalian organization will have emerged if subsequent results confirm the predominantly aversive effects of stimulation in these loci in birds. Phillips<sup>14</sup> found that electrical stimulation of the septal area in six mallard ducks yielded "escape" responses, and this provides good support for the present findings.

The demonstration of self-stimulation in three such distantly related classes of animal as osteichthyes, aves and mammalia provides evidence for the generality of the phenomenon, and investigations of other functions of pathways in which it occurs may help to clarify the significance of this type of reward.

This work was supported by grants from the U.S. Air Force Office of Scientific Research and the National Institute of Mental Health of the U.S. Public Health Service, and was carried out while I held a U.K. Medical Research Council scholarship.

## Effect of Magnetic Fields on Reaction Time Performance

In previous investigations<sup>1,2</sup> we indicated some significant empirical relationships between selected geophysical parameters and gross measures of human behaviour. The present investigation attempts to demonstrate the effects of artificially produced magnetic fields on a standard, relatively uncomplicated, psychomotor task, simple reaction time.

In our initial attempt, twin Helmholtz coils, 14.5 in. in diameter, were mounted in a concealing wooden frame to provide an 11.5 in. coil interspace. The frame, vertically movable, was attached to a wooden chair so that seated subjects, using a chin rest, could have the cerebrum approximately at the centre of the transverse magnetic fields. A gaussmeter probe was mounted in the wooden frame so as to monitor constantly the magnetic field at 1-2 in. above the centre of the subject's head. In a darkened room, each subject was instructed to press and promptly release a telegraph key, mounted on a lapboard, as quickly as possible after the appearance of an eye-level red light 7 ft. away. Three experiments were conducted: the first with equipment as described and visual read-out of a timer, the second with equipment as described but with an automatic print-out timer and an added oscillator, and the third with more efficient, commercially fabricated coils and heavier power supply. It should be cautioned that all gauss levels mentioned in these experiments reflect not absolute levels of magnetic intensity to which a subject is exposed, but those levels over and above the naturally occurring magnetic field intensity already extant in the experimental area. Further, because of the lack of field homogeneity in such a large interspace with 14 in. coils and the need to keep the probe 1 or 2 in. above the subject's head, the centre of the force field tended to give field strengths approximately one third greater than was read from the gaussmeter.

In the first experiment, steady state fields of 5 and 17 gauss, levels considerably greater than those required in natural geomagnetic activity for the designation of "severe" storm, were used with eighteen male hospitalized schizophrenic subjects, 22-49 years of age. No statistically significant effects on reaction time performance by application of steady state magnetic fields could be demonstrated, and so this approach was abandoned in favour of modulated fields.

In the second experiment, thirty male clinically normal subjects, 19-32 years of age, were randomly placed in one of three groups of ten subjects each: a control group; a group subjected to a sinusoidally modulated field of 5-11 gauss at 0.1 c/s; or a third group exposed to a similarly modulated field, but at 0.2 c/s. The three groups did not differ significantly in chronological age. The upper limit of 11 gauss was set by the capacity of the equipment used. The modulating frequencies selected were based on observations of (a) naturally occurring periods of oscillation in the cerebral direct-current potentials of animal and human subjects undergoing changes in levels of consciousness<sup>3</sup>, and (b) the enhancement of physiological effect by low frequencies (0.1-10 c/s) when alterations of consciousness have been induced by application of exogenous direct currents<sup>4</sup>. Each subject had two practice reaction time trials followed by fifty trials with 5 sec between them. Modulated fields were obtained by coupling a low frequency sine wave generator to the coil system through a solid state mixer-follower circuit.

In the initial analysis of the findings of the second experiment, the fifty reaction time trials of each subject were divided into five blocks of ten trials each and the median for each block of trials determined. Thus, there were three groups of ten different subjects each, with each subject providing five median scores. The data were submitted to analysis of variance in accordance with designs for multifactor experiments with repeated meas-

Fig. 1. Reaction time as a function of blocks of trials in male subjects. —, 0.2 c/s; ---, 0.1 c/s; ····, control.

urements<sup>5</sup>. Fig. 1 plots the sum of reaction time medians for all subjects in a group as a function of trial blocks. An *F*-test applied to all fifty trials, the last thirty trials, and the last twenty trials, gave values of 3.26, 2.90 and 2.62, respectively (d.f. 2, 27), which indicated differences approaching significance ( $P < 0.10$ ). For the last forty trials and the last ten trials the *F*'s calculated between groups were 3.45 and 3.58 (d.f. 2, 27); they were statistically significant ( $P < 0.05$ ). The Scheffé method<sup>6</sup> was applied to test the differences between the means of the three conditions and revealed that the 0.2 c/s condition was significantly different ( $P < 0.05$ ) from a combination of the other two. The findings encouraged the use of a more sensitive design using each subject as his own control. Twelve subjects were called back and two additional fifty trial reaction time performances were obtained from each so as to provide a counter-balanced design with two subjects in each of the possible six sequences of conditions. A minimum of 24 h elapsed between each condition in a sequence for every subject. The median of each block of ten reaction time trials was obtained for each subject. The sum of the medians provided a single figure indicating each subject's performance in each condition. Fig. 2 shows the performance of the twelve subjects, as a group, in each of the three conditions during each block of trials. The findings were subjected to analysis of variance in accordance with designs for single-factor experiments with repeated measures<sup>5</sup>. For the last thirty trials, last twenty trials, and last ten trials, each combined, *F*'s of 3.75, 4.21 and 4.66, respectively (d.f. 2, 22), indicated statistically significant differences ( $P < 0.05$ ). Again, the Scheffé method indicated that reaction time performance means in the 0.2 c/s condition differed significantly ( $P < 0.05$ ) from a combination of the means of the other two conditions. For all fifty trials and for the last forty trials combined, *F* values (d.f. 2, 22) of 3.06 and 3.36 approached statistical significance ( $P < 0.10$ ).

The third experiment replicated the design of the second experiment, but with thirty female subjects, 17-40 years of age. A complete wooden booth held the concealed commercially fabricated Helmholtz coils so as to provide an 11 in. coil interspace. A fixed wooden chair, movable chin rest, and seat platforms of various thicknesses enabled the subject's head to be close to the horizontal centre of the magnetic field. The magnetic probe, concealed in a wooden container in the roof of the booth, was about 2 in. from the subject's head. The coils were

powered by a d.c. power supply of 1 kW input and capable of 50 amp, 22.5 V output. Desired modulations could be accomplished by connecting an externally powered oscillator directly to the power supply.

Analysis of the data derived from assigning the subjects randomly to the three groups of ten each indicated that although differences were in the expected direction, they were not statistically significant. Fig. 3 shows the sum of the reaction time medians for all subjects in a group as a function of trial blocks. As previously, the more sensitive design was used by calling back twelve subjects and exposing each to the other two conditions of the experiment. Again, this provided a completely counter-balanced design using each subject as her own control. Fig. 4 shows the performance of the twelve female subjects as a group in each of the three conditions during each block of trials. When the data were subjected to analysis of variance all fifty trials, as a block, yielded an  $F$  of 3.49 (d.f. 2, 22) which was statistically significant ( $P < 0.05$ ). The Scheffé method indicated that the effects of the 0.2 c/s condition were significantly different ( $P < 0.05$ ) from those in the 0.1 c/s condition.

Fig. 2. Reaction time as a function of blocks of trials in male subjects used as their own controls. Symbols as in Fig. 1.

Fig. 3. Reaction time as a function of blocks of trials in female subjects. Symbols as in Fig. 1.

Fig. 4. Reaction time as a function of blocks of trials in female subjects used as their own controls. Symbols as in Fig. 1.

In general, then, the findings indicate that experimentally produced modulated magnetic fields can significantly affect reaction time performance.

## GENERAL

### Polyplanar Hip Joint for Use in Lower Limb Bracing

CHILDREN with nervous or muscular disorders affecting the movements of the trunk and lower limb sometimes have great difficulty in walking or learning to walk. External support may be provided by long callipers fitting into the heels of the boots and extending upwards to a padded metal strap around the waist. A simple hinge joint at the level of the hip (joint) allows the legs to swing in one vertical plane only. The complexity of normal walking is highlighted when a child attempts to move in such an apparatus, for the pelvis cannot rotate around a vertical axis through the hip joint of the supporting leg during the swinging phase of the other leg. The patient therefore progresses by pivoting his body around an axis passing through the ball of the supporting foot. This produces the abnormal foot positions relative to the line of march and the pelvis, which are shown in Fig. 1a and b. Fig. 1b shows that the foot bearing the weight ( $A$ ) must pivot through an angle equal to that of the pelvic swing ( $BAC$ ). In normal walking (Fig. 1a) the position of the foot remains unaltered relative to the line of march, because the necessary rotation of the lower limb has taken place at the hip joint.

Fig. 1. AB and AC indicate the frontal plane of the pelvis.

Fig. 2. a, Sitting hinge unlocked and flexed to 90° (right side); b, sitting hinge locked for walking (left side).

The anatomical movements relevant to the subsequent discussion take place at the hip joint and can be summarized as follows.

(1) Movement in an antero-posterior plane: a, forwards—flexion; b, backwards—extension.

(2) Movement in a coronal or transverse plane: a, away from the mid-line—abduction; b, towards the mid-line—adduction.

(3) Movement taking place about a vertical axis: a, rotation causing the kneecap to turn inwards—internal rotation; b, rotation causing the kneecap to turn outwards—external rotation.

## Design

Many handicapped children have a limited capacity to forget established skills and replace them with new skills. It is therefore important that they should learn to walk in the easiest and most natural way. We concluded that a near-normal rotation of the leg during forward and backward movement could be induced by using an additional joint the axis of which was directed outwards and downwards, instead of being horizontal. This design also allows a small amount of movement away from the line of march, so that the walking sequence approximates more closely to the normal pattern. To allow a normal sitting position, the standard (horizontal axis) hinge is fitted above the walking hinge joint (Fig. 2), but the former is locked during standing and walking.

## Kinematic Analysis

The action of the hinge used in forward and backward movement was analysed by considering the system of axes defined in Fig. 3. The hinge axis is  $X$ , and the axes perpendicular to it are designated  $Y$  and  $Z$ . Axes representing swing, rotation and abduction ( $x$ ,  $y$  and  $z$ , respectively) are obtained from  $X$ ,  $Y$  and  $Z$  by a negative rotation of magnitude  $\alpha$  about  $Z$ .

The co-ordinates of the point  $P$  are

$$\left. \begin{aligned} X &= -l \sin \alpha \\ Y &= -l \cos \alpha \cos \theta \\ Z &= -l \cos \alpha \sin \theta \end{aligned} \right\} \quad (1)$$

where  $\theta$  is the angular displacement of the hinge. In general, co-ordinate transformation by a rotation  $-\alpha$  about  $Z$  gives:

$$\left. \begin{aligned} x &= X \cos \alpha - Y \sin \alpha \\ y &= Y \cos \alpha + X \sin \alpha \\ z &= Z \end{aligned} \right\} \quad (2)$$

and in this case, the co-ordinates of  $P$  in terms of  $x$ ,  $y$  and  $z$  are obtained by substituting equations (1) in equations (2).

$$\left. \begin{aligned} x &= l \sin \alpha \cos \alpha (\cos \theta - 1) \\ y &= -l (\sin^2 \alpha + \cos^2 \alpha \cos \theta) \\ z &= -l \cos \alpha \sin \theta \end{aligned} \right\} \quad (3)$$

Consider the angular displacements about  $x$ ,  $y$  and  $z$  as defined for this configuration in Fig. 4 (a-c). From this diagram and equations (3)

$$\left. \begin{aligned} \varphi_x &= \tan^{-1} \frac{z}{y} = \tan^{-1} \frac{\cos \alpha \sin \theta}{\sin^2 \alpha + \cos^2 \alpha \cos \theta} \\ \varphi_y &= \tan^{-1} \frac{x}{z} = \tan^{-1} \frac{\sin \alpha (1 - \cos \theta)}{\sin \theta} \\ \varphi_z &= \tan^{-1} \frac{x}{y} = \tan^{-1} \frac{\sin \alpha \cos \alpha (1 - \cos \theta)}{\sin^2 \alpha + \cos^2 \alpha \cos \theta} \end{aligned} \right\} \quad (4)$$

It can be seen that  $\varphi_x$  and  $\varphi_y$  change signs when  $\theta$  changes sign, but  $\varphi_z$  remains positive for all values of  $\theta$ . Physically, this means that hip flexion is accompanied by

Fig. 3.

external rotation, and extension by internal rotation; adduction never occurs.

To minimize abduction, an appropriate value for  $\alpha$  needs to be selected by setting the derivative of  $\varphi_z$  with respect to  $x$  equal to zero, which leads to the condition

$$\tan^2 \alpha = \cos \theta$$

For small values of  $\theta$ ,  $\cos \theta$  is almost unity and, ignoring the negative root,  $\alpha = \pi/4$ . With this value of  $\alpha$ , equation (4) for the angular displacement becomes

$$\left. \begin{aligned} \varphi_x &= \tan^{-1} \frac{\sqrt{2} \sin \theta}{1 + \cos \theta} = \tan^{-1} \sqrt{2} \tan \frac{\theta}{2} \\ \varphi_y &= \tan^{-1} \frac{1 - \cos \theta}{\sqrt{2} \sin \theta} = \tan^{-1} \frac{1}{\sqrt{2}} \tan \frac{\theta}{2} \\ \varphi_z &= \tan^{-1} \frac{1 - \cos \theta}{1 + \cos \theta} = \tan^{-1} \tan^2 \frac{\theta}{2} \end{aligned} \right\} \quad (5)$$

Using these expressions,  $\varphi_x$ ,  $\varphi_y$  and  $\varphi_z$  are plotted against  $\theta$  in Fig. 5.

In practice, a swing of  $\pm 15^\circ$  should be associated with  $\pm 5^\circ$ – $10^\circ$  of rotation, while abduction or adduction should be negligible. The graph (Fig. 5) shows that with the axis of rotation angled downwards and outwards by  $45^\circ$ , a  $15^\circ$  swing produces  $8^\circ$  of outward rotation, and a  $-15^\circ$  swing  $8^\circ$  of inward rotation, whereas abduction, being minimal for low values of  $\varphi_x$  is only  $2^\circ$  during the same amount of movement. The practical value of such joints is at present being investigated using assessment techniques evolved at the Cerebral Palsy Physical Assessment Centre, Guy's Hospital.

A polyplanar joint, the movement of which approximates more closely to that of a hip joint, should show a number of advantages over the conventional simple hip joint currently used in long leg braces. The application

Fig. 4.

Fig. 5.

of engineering theory to the problem demonstrates how valuable co-operation between university departments can be in reducing the time spent on physical trials of such apparatus.

## Negentropy, Information and the Feeding of Organisms

IN a recent reply to Büchel, concerning entropy and information in the universe, Popper<sup>1</sup> persists in the use of a biological example which appears to be incorrect. This concerns the developing birds' eggs which "appear to produce structural negentropy by increasing their structural organization; they are, as far as we know, "fed", in Schrödinger's sense, exclusively on heat (that is, on entropy)". This does not constitute a counter example to Schrödinger's views<sup>2</sup> because the developing embryo in the egg "feeds" on the negentropy of the yolk; this conversion process, in common with most biological energy conversion processes, is not very efficient and in the course of it entropy (as heat) is generated. The purpose of incubation is to reduce the rate of flow of heat away from the egg which is poorly insulated, no doubt inevitably so as a consequence of the structural requirements for gas exchange. Thus over the whole period of incubation there is a net loss of radiant energy from the egg and it is therefore misleading to suggest, as Popper does, that the egg has fed on entropy. To have asked of Schrödinger (as Popper requires) that he say something of organisms which distinguishes them from heat engines was scarcely possible in the strictly thermodynamic context of Schrödinger's famous remark, because it would have required going beyond the then available limits of thermodynamics to say something about the form or information content of the received energy.

Photosynthetic autotrophic organisms are entropy feeders which canalize the entropy of sunlight into the thermodynamic and structural negentropy of their own structures. The entropy feeding of these organisms can be said to be achieved ultimately by the agency of the informational (that is, structural) negentropy represented in the replicative and renewal templates within their cells. Büchel<sup>3</sup>, however, makes extravagant claims about the relationships of this structural negentropy to the thermodynamic entropy increase of a system, raising to the level of a general principle the proposition that "whenever structural negentropy is produced, the thermodynamic entropy must increase by at least the same amount". Even if it is accepted as proved that in the chosen example of a watchmaker assembling a watch, putting in as he does so  $n$  bits of information, the attendant increase in thermodynamic entropy will be at least  $Kn \log 2$  cal/grad, there is no evidence that a similar relationship will hold for the structural negentropy generated by a living organism. Taking the case of even the simplest organisms growing on defined media we do not have sufficient knowledge of the direction and magnitude of radiation and chemical energy exchange with the environment or of how to approach the problem of a valid estimate of their information content, even to embark on the measurement of this relationship, much less to claim its probable general validity.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, March 6

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. M. K. McPhun: "U.H.F. Tunnel-Diode Amplifier"; Dr. D. L. Hedderly, Mr. J. Hooper and Mr. M. K. McPhun: "Short-Hop Radio-Relay Systems Using Tunnel-Diode Repeaters".

UNIVERSITY COLLEGE LONDON (in the Chemistry Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. L. S. Bosanquet: "The Sum of an Unconvergent Series". (Inaugural Lecture.)\*

UNIVERSITY OF LONDON (in the Main Lecture Theatre, Physics Building, Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. Sir Vincent Wigglesworth, F.R.S.: "Insect Hormones" (further lectures on March 7 and 8).\*

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. D. A. Dowden: "The Coherence of Pure and Applied Heterogeneous Catalysis".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. R. A. Hibbert: "Mongolia Today".

## Tuesday, March 7

UNIVERSITY OF LONDON (in the Wolfson Lecture Theatre, Royal Postgraduate Medical School, Du Cane Road, London, W.12), at 5 p.m.—Prof. Sir Dugald Baird: "The Prevention of Perinatal Death".\*

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the Inst. of Mech.E., at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. J. Spurgin and Mr. R. L. Carstairs: "Overall Station Control at Hunterston".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. R. King: "Heat" (Lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties. To be repeated on March 8, 14 and 15.)

UNIVERSITY OF ASTON IN BIRMINGHAM (in the Great Hall of the University, Gosta Green, Birmingham 4), at 5.30 p.m.—Prof. Holmes: "The Advancement of Knowledge in Civil Engineering" (Inaugural Lecture).\*

INSTITUTE OF METALS (at 17 Belgrave Square, London, S.W.1), at 6 p.m.—Sir Henry Jones: May Lecture.

PLASTICS INSTITUTE, LONDON SECTION (at Imperial Chemical House, Millbank, London, S.W.1), at 6.30 p.m.—Dr. H. J. Sharp: "Plastics in Domestic Appliances".

## Tuesday, March 7—Thursday, March 9

INSTITUTE OF METALS (at Church House, Great Smith Street, Westminster, London, S.W.1)—Spring Meeting and Meeting of the British Joint Corrosion Group.

## Wednesday, March 8

PLASTICS INSTITUTE (at the Institution of the Rubber Industry, 4 Kensington Palace Gardens, London, W.8), at 2.30 p.m.—Mr. D. R. Reid: "Impact Testing and Brittle Failure".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Captain Lionel Munk: "The Value of Inland Waterways".

UNIVERSITY OF LONDON (at the Institute for Diseases of the Chest, Brompton Hospital, London, S.W.3), at 5 p.m.—Dr. Lynne Reid: "The Clinical Diagnosis and Classification of Emphysema".\*

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. P. Penfield: "Thermodynamics of Electrical Networks".

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. E. I. Lowe: "Computer Control of Chemical Processes".

UNIVERSITY OF LONDON (at Senate House, London, W.C.1), at 5.30 p.m.—Dr. P. Gaasstra (Wageningen): "The Relation Between Photosynthesis and Crop Growth".\*

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dame Honor Fell, F.R.S.: "The Effect of Environment on Bone in Culture". (Second of three lectures on "The Scientific Basis of Dentistry" organized by The British Postgraduate Medical Federation.)\*

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College, London, S.W.7), at 6 p.m.—Mr. T. N. Reynolds: "Acoustics in the Underwater Environment".

## Wednesday, March 8—Thursday, March 9

ZOOLOGICAL SOCIETY OF LONDON AND THE MALACOLOGICAL SOCIETY OF LONDON (at the Zoological Society of London, Regent's Park, London, N.W.1), at 10 a.m. daily—Symposium on "Studies in the Structure, Physiology and Ecology of Molluscs".

## Thursday, March 9

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.20 p.m.—Mr. B. C. Brookes: "Scientific Information and the Computer".\*

MINERALOGICAL SOCIETY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

INSTITUTE OF PETROLEUM, ECONOMICS AND OPERATIONS GROUP (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. J. P. MacCarthy: "Recent Developments in Home Heating".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion Meeting on "The Synchronization and Resynchronization of Alternators" opened by Mr. B. J. Cory.

UNIVERSITY COLLEGE LONDON (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Kensei Cheng (New York University School of Medicine): "Fast and Slow Fibres in Mammalian Extraocular Muscles".\*

## Thursday, March 9—Friday, March 10

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Dr. T. E. Calverley: "High-Voltage D.C. Transmission" (Silvanus P. Thompson Lecture).

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 10.30 a.m. daily. Discussion Meeting on "The Origin and Treatment of Noise in Industrial Environments" organized by Mr. E. J. Richards.

## Friday, March 10

SOCIETY FOR WATER TREATMENT AND EXAMINATION (at the Royal Hotel, Woburn Place, London, W.C.1), from 9.30 a.m. to 5.30 p.m.—Symposium on "Water Filtration".

ASSOCIATION OF APPLIED BIOLOGISTS (in the Lecture Hall of the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 10.50 a.m.—Symposium on "Selective Phytotoxicity".

UNIVERSITY OF LONDON (in the Beveridge Hall, Senate House, London, W.C.1), at 12 noon—Memorial Meeting to commemorate the life and work of the late Prof. Frank Cunliffe Ormerod.\*

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W.1), at 1 p.m.—Dr. R. B. Cundall: "Photochemistry of Some Olefin Containing Systems".

BRITISH SOCIETY FOR INTERNATIONAL HEALTH EDUCATION (at the Goldsmith's Hall, Foster Lane, London, E.C.2), at 5.30 p.m.—Sir John Wolfenden, C.B.E., and Dr. Victoria Garcia: "Education—Health's New Dimension".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. R. W. White: "Broadband Transmission by Radio and Cable".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. G. D. Sims and Dr. B. H. Venning: "The Future Education of Electronic Engineers".

UNIVERSITY OF LONDON (at Royal Holloway College, Englefield Green, Surrey), at 8.15 p.m.—Dr. T. F. Gaskell: "Looking for Gas in the North Sea".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. R. L. F. Boyd: "Space Science and the Astronaut".

## Saturday, March 11

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. Michael H. Day: "Man or Ape?—Research into *Homo habilis*".\*

## Monday, March 13

SOCIETY OF CHEMICAL INDUSTRY, OILS AND FATS GROUP (joint meeting with the Food Group and Colloid and Surface Chemistry Group, at 14 Belgrave Square, London, S.W.1), at 2.30 p.m.—Meeting on "Emulsions and Emulsifiers in the Food Industry".

UNIVERSITY OF LONDON (at the School of Oriental and African Studies, London, W.C.1), at 5 p.m.—Prof. Jean-Luc Chambard (Paris): "Atlas of an Indian Village. 1, The Village: Society and Economy".

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. K. Mothes (East Berlin): "On Cytokinins" (further lectures on March 14 and 15).\*

PLASTICS INSTITUTE, LONDON SECTION ENGINEERING SUB-GROUP (at the Coachmakers Arms, 88 Marylebone Lane, London, W.1), at 6.30 p.m.—Mr. J. Barnes: "Industrial Design as Applied to Machinery".

## Monday, March 13—Friday, March 17

INSTITUTION OF CIVIL ENGINEERS, THE BRITISH NUCLEAR ENERGY SOCIETY AND THE JOINT BRITISH COMMITTEE FOR STRESS ANALYSIS (at Church House, Great Smith Street, Westminster, London, S.W.1)—Conference on "Prestressed Concrete Pressure Vessels".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2)—Conference on "Air Traffic Control".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER (zoologist, physiologist or pharmacologist, preferably with an interest in comparative endocrinology or general physiology) in the DEPARTMENT OF BIOLOGICAL SCIENCES—The Staff Officer, The University of Aston in Birmingham, Gosta Green, Birmingham, 4, quoting Ref. 537/2 (March 8).

LECTURER IN CIVIL ENGINEERING—The Principal, Lanchester College of Technology, Priory Street, Coventry (March 13).

RESEARCH ASSISTANT in the DEPARTMENT OF GEOLOGY to work under the direction of Mr. F. J. Fitch in the field of geochronology—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (March 13).

RESEARCH ASSISTANT (with an honours degree in geography or a related field with some experience in field surveying and mathematical geography, and preferably a knowledge of sediment analysis) in the DEPARTMENT OF GEOGRAPHY, to work on the bathymetric survey of Loch Leven, Kinross—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (March 13).

LECTURER (experienced in the fields of solid mechanics, dynamics and design) in AGRICULTURAL ENGINEERING—The Registrar, The University, Newcastle upon Tyne, 2 (March 15).

POSTGRADUATE RESEARCH ASSISTANT IN STRUCTURAL CHEMISTRY to work on a Science Research Council supported project entitled "A Preparative and Kinetic Study of the Halogenation of Co-ordinated Ligands"—The Registrar, University of Bradford, Bradford, 7, Yorkshire (March 15).

ASSISTANT LECTURER IN BIOCHEMISTRY—The Secretary, Queen's College, Dundee, Scotland (March 18).

LECTURER (with working experience in the techniques of radiometric rock-dating) in the SUB-DEPARTMENT OF GEOPHYSICS—The Registrar, The University, Liverpool, quoting Ref. RV/406 (March 18).

CHAIR OF MATHEMATICAL STATISTICS AND CHAIR OF THEORETICAL PHYSICS—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (March 20).

ASSISTANT LECTURER IN PSYCHOLOGY—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (March 24).

SENIOR LECTURER (graduate of an internationally recognized veterinary school with considerable experience and interest in teaching and research at university level, and preferably tropical or sub-tropical experience) in the DEPARTMENT OF ANIMAL SCIENCE, University of Ghana—The Assistant Registrar, Universities of Ghana Office, 15 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (March 27).

EXPERIMENTAL OFFICER in the DEPARTMENT OF BOTANY for duties which will include upkeep of the Departmental Herbarium and assistance with teaching in taxonomy and research—The Secretary, Academic Council, The Queen's University, Belfast, Northern Ireland (March 31).

LECTURER (preferably with experience of West African or tropical conditions) in AGRICULTURAL BIOCHEMISTRY AND NUTRITION, with particular reference to carbohydrate and energy metabolism studies, in the DEPARTMENT OF AGRICULTURAL CHEMISTRY AND SOILS, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (March 31).

RESEARCH FELLOW (graduate with a research degree or equivalent experience) in the SEDIMENTOLOGY RESEARCH LABORATORY, GEOLOGY DEPARTMENT, to conduct an N.E.R.C. sponsored investigation into the sedimentology (including geochemistry, physical properties and clay mineralogy) of facies variation in the Great Oolite Series of the Malmesbury area—The Assistant Bursar (Personnel), The University, Reading (March 31).

SENIOR LECTURER (veterinary surgeon with experience of modern methods for the control and development of animal health and animal production, and preferably some teaching experience) in ANIMAL HEALTH in the DEPARTMENT OF ANIMAL HUSBANDRY AND HYGIENE—The Secretary, The Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (March 31).

LECTURER (with a good degree in forestry or engineering with post-graduate experience in wood science, and preferably some experience in industry) in WOOD SCIENCE in the DEPARTMENT OF FORESTRY—The Registrar, University College of North Wales, Bangor, North Wales (April 1).

ASSISTANT LECTURERS or LECTURERS in the DEPARTMENT OF PHYSICS (lines of research include photo electronics and image intensifiers; low temperature physics; magnetic alloys; dielectrics and semi-conductors, experimental and theoretical)—The Registrar, University College of North Wales, Bangor, North Wales (April 3).

LECTURER (graduate with some experience of tropical agriculture) in CROP HUSBANDRY at the University of Malawi—The Inter-University Council, 33 Bedford Place, London, W.C.1 (April 3).

SENIOR LECTURER or LECTURER in the DEPARTMENT OF PREVENTIVE AND SOCIAL MEDICINE, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (April 3).

UNIVERSITY LECTURER IN BIOCHEMISTRY—The Administrator, Department of Biochemistry, University of Oxford, South Parks Road, Oxford (April 3).

LECTURER (preferably with an interest in mycology, plant ecology or plant physiology) in BOTANY at University College, Dar es Salaam, University of East Africa—The Inter-University Council, 33 Bedford Place, London, W.C.1 (April 5).

SENIOR LECTURER and a LECTURER in ANATOMY—The Secretary, The Medical College of St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (April 14).

RESEARCH DEMONSTRATOR (with a good honours degree in geology with special interests in stratigraphy and structural geology and/or petrology) in the DEPARTMENT OF GEOLOGY—Prof. J. G. C. Anderson, Department of Geology, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (April 15).

ASSISTANT LECTURER (science graduate in microbiology) in BACTERIAL AND VIRAL GENETICS—The Professor of Bacteriology, The University, Bristol.

DEMONSTRATORS or ASSISTANT LECTURERS in the DEPARTMENT OF HUMAN BIOLOGY AND ANATOMY—Prof. R. Barer, The University, Sheffield.

MASTER to teach CHEMISTRY to all levels—The Headmaster, The King's School, Canterbury, Kent.

MYCOLOGIST (with good taxonomic knowledge and physiological interests) for work on production of ergot alkaloids and other biologically active substances of fungal origin by fermentation methods—The Secretary, Biochemistry Department, Imperial College of Science and Technology, London, S.W.7.

## MACHINE AT THE READY

THE British Government must now have finished the job of assembling the kind of machinery necessary for the administration of science and technology. This, at least, is what everybody must hope, for there is always a danger that reorganization, for all the inconvenience which it causes, will seem preferable to constructive activity. But now the old Ministry of Aviation is fast losing its identity within the Ministry of Technology. The Central Advisory Council on Science and Technology under Sir Solly Zuckerman is said to have met around a table on two occasions. On another stage, the Select Committee of the House of Commons on Science and Technology has begun to function. One way and another, the months ahead are likely to be full of bustle. It would be foolish as well as churlish to complain that nothing much has happened yet.

That said, it is only reasonable to keep in mind the doubts which conspire to suggest that the new machinery may prove to be deficient. Within the Ministry of Technology, it will take courage as well as good sense to bring about a rapid devolution of activity from government establishments to industry and the universities. From what the ministry is now saying in public, it can see what needs to be done. It remains to be seen whether it will be able to act as sensibly as it talks. The advisory committees will also need watching in the months ahead. The Council for Scientific Policy under Sir Harrie Massey has done so well in fighting for funds for the research councils that complacency may be the biggest danger. The Central Advisory Council will have more difficult battles on its hands, and its procedures are deficient in at least two important ways. For one thing, its proceedings will be private, which means that it will be less able than it should be to enlist informed opinion in its support. The fact that the Royal Society as such will not now be represented on the council is wise, at least as far as the society is concerned, but yet another reason for fearing that the advisory council will be working in a vacuum. Then it is not clear whether the council is strong enough, and well placed enough, to bring defence research and development fully under the same umbrella as civil work. The transfer to the Ministry of Technology of the Ministry of Aviation, traditionally the procurement agency for the services, will help, but the single representative of the Ministry of Defence on the new council may be a sufficient assurance that the services will accept the recommendations of the Central Advisory Council without further argument.

As luck will have it, the House of Commons committee may help to make good some of these deficiencies. It is bound, of course, to be some time before the committee has won such a high reputation for itself

that government departments will wait for its observations before making new policies, but the way in which the Select Committee on the Nationalized Industries seemed last week to have become one architect of the new policy on the organization of the Post Office is something to work towards. But, from the beginning, the committee on science and technology will be able to do valuable work by uncovering the arguments by which government departments and their committees suggest new policies or justify the old. Ministers and officials, who in Britain consistently seek to still criticism with secrecy, only ensure that it is often ill-informed. So everybody will be better off if the new committee of the House of Commons can be an instrument for enlightenment about the roots of policy. Certainly it should not fall in with the expectation of some officials that it will stick to uncontroversial matters. It should also take a particular interest in the machinery of government, which means that Sir Solly Zuckerman should be a frequent witness.

## PLAN FOR OCEANOGRAPHY

THE committee of the National Academy of Sciences on oceanography has produced a disappointing report (see page 957). Although it may give pleasure and profit to readers looking for new branches of research in which to work, it will not do much to help decide how the United States administration should seek to spend money on the development of oceanography. The chief reason for complaint is that the committee set out to formulate a set of principles intended to keep some kind of balance between oceanographic research of various kinds. There is, unfortunately, a danger that the rules which have now been suggested may become an obstructive precedent not merely in oceanography but in other fields as well.

The essence of the scheme put forward by the committee is an apparently tidy distinction between research of different kinds. The committee would like to see the National Science Foundation shoulder responsibility for what is called "discipline-oriented research", and the other agencies of the United States Government made responsible for short-term and long-term research which is "mission-oriented". The choice of short-term projects should be determined by "external considerations" including cost-benefit analysis, and, to make sure that the agencies do not put all their energy into a search for short-term benefits, the committee would like there to be an agreement on the ratio of short-term and long-term work sponsored by the

agencies. All this is put forward as a new "rationale of budget making". The trouble is that it is not a rationale but the opposite—an attempt to avoid thinking hard about individual proposals for research.

The most immediate difficulty is that of making a meaningful distinction between largely academic research sponsored by the National Science Foundation and the long-term work which agencies such as the Navy Department are encouraged to support in the belief that it will ultimately bring practical advantages. Thus the U.S. Navy is just as likely as a university research unit to decide that a long-term study of the movement of ocean currents would be worthwhile. This, indeed, is why the U.S. Navy has such a splendid record in supporting long-term research. Presumably there was once a committee paper setting out just how the navy would in the long run benefit from the successful studies of X-ray emission from the Sun which have been sponsored by the Office of Naval Research.

There is a real danger that the artificial distinction of the kind now proposed would turn out to be cramping either for the mission-oriented agencies or for the National Science Foundation. It is even more unrealistic, however, to suppose there can ever be a predetermined ratio of the cost of long-term and short-term research supported by one agency. This is bound to be an exceedingly arbitrary business and open to abuse as well. What the committee should have asked itself is how arrangements should be made to see that long-term research programmes and grant-giving are properly co-ordinated, and what arrangements there should be for stabilizing the scale of financing for long-term work against the fluctuations of enthusiasm for short-term goals. It would be an important step in this direction if the National Science Foundation were given a greater share of the money for oceanography. The councils created by the White House in July last year should help with co-ordination. But simple rules of thumb will create more problems than they solve.

## MARKING TIME AT GENEVA

It is entirely welcome that the nuclear powers have decided to wait for further discussions before tabling their draft treaty on the non-proliferation of nuclear weapons at the United Nations Disarmament Committee at Geneva. Three weeks ago (see *Nature*, **213**, 641) the nuclear powers seemed unreasonably optimistic about the chances of a quick agreement. Events have clearly taught them a little caution—and have set in train a flurry of diplomatic activity. Sir Solly Zuckerman has been in Bonn, doing his best to allay German anxieties about the Treaty. Lord Chalfont, the minister of state responsible for disarmament at the Foreign Office, has been trying to do the same in Brussels, where Euratom is at once offended and threatened by the suggestion that some other agency—the International Atomic Energy Agency at Vienna—

should assume international responsibility for safeguards and inspection. Other nuclear powers are engaged on the difficult discussions with India about the kinds of political guarantees which would at once be practicable and feasible. This is one reason why there was a welcome for the announcement a week ago that the United States and the Soviet Union have agreed to hold discussions on measures to limit their own deployment of strategic weapons. A tacit agreement between two similarly placed powers is much more easily arrived at than an agreement affecting everybody.

That, however, is no reason for giving up hope of what will happen at Geneva. The first need is to create a sense of realism there. It seems now to be acknowledged that a treaty to prevent the spread of nuclear weapons must be backed up by the most rigorous forms of international inspection, and the United Nations Assembly made it plain last year that the IAEA should be the instrument of choice. But the agency is only now beginning to stretch its wings. Although there are now more than fifty reactors on the books of the agency's inspectors, only a handful of these are power reactors. So far, they only cover one plutonium separation plant, and rules to cover diffusion plants, fabrication plants and uranium mines are not yet in operation. Nobody is to blame for this, but it is bound to be several years before comprehensive arrangements are worked out. That time scale must be reckoned with by the nations at Geneva. If they are lucky and get a quick agreement, they may have to put up with a provisional safeguards system. The delay will only be an insuperable obstacle if they do not know it in advance.

The political problems at Geneva are just as daunting, although it is pleasing that much less is now heard of the loss of the alleged uncovenanted benefits which could be expected to flow from a military programme of nuclear development. This view, of course, is nonsense. The argument about commercial secrecy, much heard in West Germany, will have less force when it is more widely recognized that research and development facilities would be less open to inspection than power plants. The argument about the place of Euratom in a system of international safeguards is less tangible, but in the long run it is unthinkable that the international agency should delegate its responsibilities for inspection to what is essentially a private organization. (That said, the existence of Euratom controls could make the task of international inspection lighter.) But the real difficulty about the treaty is its asymmetry. Whatever language may be used, the draft as it stands must seem to the non-nuclear powers to be a means of perpetuating the nuclear status of the others. Until the nuclear powers find some way of modifying this impression, they are not likely to get a treaty. Their insistence on rigorous inspection will only make it easier for the non-nuclear powers to retort by asking for a cut-off of production. On the face of things, the nuclear powers will be hard pressed to give a convincing reason why this should not be combined with the provisions on non-proliferation.

# NEWS AND VIEWS

## Post Office Research

THERE is some sharp criticism of the research programme of the British Post Office in the report of the House of Commons Select Committee on the Nationalized Industries, published a week ago (*The Post Office*, Volume 1, *Report and Proceedings*, Cmnd 340, H.M.S.O., 16s.). The select committee considers that the time is ripe for a "major review" of the scale on which research and development is being carried out. Although it acknowledges that the Post Office is spending 2.5 per cent of its revenue from telecommunications on research and development (adding up to £4.9 million a year with another £0.49 million for research on the postal services), and that the ratio of the spending at the Bell Telephone Laboratories in the United States is a similar proportion of the total revenue of the Bell System, the committee nevertheless suspects that research by the British Post Office may be no more than adequate. It draws particular attention to the need for "long-term research and development on telecommunications systems", and hopes that the transfer of the Post Office Research Station from London to Suffolk will provide an opportunity for basic research on new devices and on the mathematical aspects of communications theory. Although the select committee has clearly listened sympathetically to the view of industry that research and development should be even more closely linked with the production of equipment, it would prefer a closer link with the operation of the telecommunications network. As things are, the value of research and development carried out by industrial companies amounts to £10 million a year, and roughly half this cost is met by the Post Office. The select committee also exhorts the Post Office to develop closer links with universities by letting more research contracts to them.

The most ominous passage in the report may well be that concerning the recruitment of staff. The committee says that there has been a shortage of graduates, particularly good ones, for several years. One consequence was that men had to be taken off the long-term development of microwave equipment to help with the design of the satellite communications station at Goonhilly in Cornwall. The select committee says that the salaries offered by the Post Office to postgraduate scientists and to graduate engineers are not competitive with those obtainable in industry.

## A Select Committee

THE new Select Committee on Science and Technology met in the House of Commons for the first time last week. The committee has a Labour chairman, Mr. Arthur Palmer, and 13 members; 7 Labour, 5 Conservative, and 1 Liberal. The Labour members are Mr. Norman Atkinson, Mr. Tam Dalyell, Dr. E. A. Davies, Mr. D. Ginsburg, Mr. R. L. Howarth, Dr. David Owen, and Mr. B. S. Parkyn, and the Conservatives are Mr. Stephen Hastings, Sir Harry Legge-Bourke, Mr. Airey Neave, Sir Ian Orr-Ewing, and Mr. David Price. The solitary Liberal is Mr. Eric Lubbock.

Several of the members have qualifications, experience, or both, in science and science-based industry. Mr. Palmer is a chartered engineer and a chartered fuel technologist; Mr. Atkinson is a design engineer; Mr. Dalyell was secretary of the Labour Party Standing Conference on the Sciences, 1962-4; Dr. Davies gained his doctorate at Cambridge for work on superconductivity, and worked as a research scientist for Associated Electrical Industries, Ltd.; Dr. Owen is a fellow of the Royal Society of Medicine, and Mr. Parkyn a plastics chemist. Of the Conservatives, Mr. Hastings is a director of Handley-Page and the author of a book which criticizes the cancellation of the TSR 2 project; Mr. Neave has many years' experience of scientific and technical committees, and is a governor of Imperial College; Mr. Price is the Conservative front bench spokesman on science and technology. Sir Ian Orr-Ewing is an Oxford graduate in physics, and the Liberals are represented by another Oxford graduate, Mr. Lubbock, who read engineering.

For a House of Commons which is thinly populated with scientists, this is a fair showing. The committee intends to meet once weekly, and the sessions will be open to the public. Deliberations started with a discussion of the British reactor programme. What the committee does not intend to do is to conduct post mortems in the manner of the Public Accounts Committee; the intention is to discuss policy before it is made, and for this purpose it can call in evidence anyone it wishes. The Select Committee on the Nationalized Industries, with a similar constitution, established a convention of never calling ministers to give evidence, but the new committee has made it clear that it will not feel bound to do the same. The committee will make its recommendations in the first place to the House of Commons, although the intention is that they will filter through and influence policy-making.

If the committee does establish a reputation and begins to influence policy in an open way, it will be welcome. The new Central Advisory Council under Sir Solly Zuckerman will be operating in private, and all that is seen of the Council for Scientific Policy is an annual report. What these committees are thinking becomes apparent only when it is too late to influence them. The new select committee has the opportunity of showing that it is not necessary to retreat behind closed doors in order to influence policy.

## More about Oceanography

EVENTS seems unkindly to have taken the gloss off the report on oceanography by the U.S. National Academy of Sciences (*Oceanography 1966, Achievements and Opportunities*, National Academy of Sciences, \$5.00). Although the responsible committee under Dr. Milton Schaeffer of the Scripps Institute of Oceanography has been at work since 1956—it issued its first report in 1959—its most recent document was on the way to the printers when the White House announced its plan to create two new public bodies for fostering the development of oceanography—the Commission on Marine Science, Engineering and Resources and the National Council on Marine Resources and Engineering Development. That step was part of a spate of activity about oceanography which included a report on the subject by the Science Advisory Committee recom-

mending, among other things, a doubling of expenditure on oceanographic research (see *Nature*, 211, 446; 1966). Although the committee says that the existence of the two new bodies will help to implement the policies it now commends, what it has to say would undoubtedly have been more influential a year ago.

Although the report is principally concerned with an attempt to describe the ways in which oceanographic research can be with advantage increased, it will be read with most attention for what it has to say about the principles on which decisions should be made for investing new funds. The committee seems to be dissatisfied with existing machinery for allocating resources, and writes of the way in which proposals for research are sometimes subjected to "reviews of previous reviews by the same reviewing bodies". It pleads for a distinction between "discipline oriented activities" and "mission oriented activities".

U.S. FEDERAL EXPENDITURE ON OCEANOGRAPHY  
(millions of dollars)

	Department of Defense	National Science Foundation	Total (all agencies)
1958	9.1	1.5	21.3
1961	31.6	7.9	62.1
1964	54.6	19.6	123.1
1967	114.9	28.5	217.5

The first category of research projects is said to include those whose object is to "increase understanding of ocean science as a field of knowledge", and for which the National Science Foundation should be the principal source of funds. (The committee recognizes that agencies such as the Office of Naval Research have played an influential part in supporting basic research in oceanography.) Among the "mission-oriented" projects the committee distinguishes some which are expected to have "near-term payoffs" and those which promise more distant results. It is afraid that long-term projects will be neglected for the sake of quick returns, and asks grant-giving bodies to keep to some more or less constant ratio of activity. In the same spirit, the committee exhorts the independent grant-giving agencies—the National Science Foundation and the Smithsonian Institute—to recognize that practically oriented research should be founded on a sufficient basis of "discipline oriented research". Further restraints on the pattern of spending are imposed by remembering, for example, that a 600 ton research vessel will require that \$1.5 million a year should be spent in the shore facilities to which the oceanographers return after their spells at sea.

## Government Social Survey

THE British Government Social Survey is to become an independent body responsible to the Treasury on April 1, 1967. Since it was set up in 1941, the survey has been part of the Central Office of Information, originally the Ministry of Information. In 1965 the report of the Committee on Social Studies under Lord Heyworth recommended that the survey should be separated from the COI because of the unavoidable weaknesses of administration. The committee considered that the services which the survey could provide were often inadequately understood by government departments, and that studies being carried out for different departments could in many cases be combined. There was also no provision in the organization of the survey for

advance planning to meet the needs of future government policy.

It is hoped that the reorganization will make it possible for the survey to take a more active part in the training of research workers in the social sciences. With an annual budget of about £400,000, the survey carries out a third of all government research in the social sciences. It is to have a new controller, Mr. T. D. Kingdom, formerly an under secretary at the Ministry of Social Security, who will report to an interdepartmental committee composed of people from the main user departments and from the Treasury.

## Some Cheer from Florence

THE Botanical Institute of Florence seems to have survived the floods of November 1966 with less damage than was at first expected. The director of the institute, Dr. Eleanora Francini Corti, says that the institute and the garden were flooded, the ground floor to a depth of 70 cm. Nevertheless the great herbaria, which are the most important collections at the institute and which were kept on the first and second floors, were quite undamaged. The underground archives were less well protected, but it seems that the inks of the oldest manuscripts have survived their submersion without damage. The newer volumes survived less well, partly because of the quality of the paper from which they were made. Stocks of the botanical journals published from Florence have been seriously damaged. As a whole, however, it seems that the flood waters which invaded the institute were not contaminated with the petroleum products which proved to be extremely damaging elsewhere in the city.

## Science Spending in New Zealand

THE New Zealand government has been doubling its expenditure on science every seven or eight years for the last three decades according to figures compiled by the New Zealand National Research Advisory Council and now published by the New Zealand Department of Scientific and Industrial Research, Wellington (*Scientific Research in New Zealand—Government Expenditure and Manpower 1926–1966*, 5s.). Even so, the total expenditure in New Zealand on scientific research by the government amounted to just under £6 million in 1966. The Department of Scientific and Industrial Research is the largest consumer of funds (£1.7 million), and agriculture takes more than a fifth of the total—a proportion which has been declining steadily over the years since the war, when more than a third of all public expenditure on research was spent on agriculture. These figures are reflected in the pattern of employment. Public service in New Zealand employs just under 1,000 people on research, with 562 of them in the Department of Scientific and Industrial Research, 255 in agriculture, and mere handfuls elsewhere except in forestry.

## Calouste Gulbenkian Foundation

DURING 1966 the Calouste Gulbenkian Foundation gave away £4,635,000 in the form of grants, £532,432 of it in Britain and the British Commonwealth. In the Commonwealth the interest of the Foundation is mainly in the arts, and about half the money spent

comes under this heading, but elsewhere the emphasis is different. In Portugal £635,225 went on science and medicine, £584,270 on education, and only £163,597 on the arts. Armenian communities throughout the world (£552,975), social and cultural projects in South America (£820,738) and gifts to charities in the Middle East and elsewhere made up the rest of the budget.

In Britain the foundation supports some fascinating projects. The University of Bristol was given a grant to study the social and psychological consequences of development and rehousing in Bristol, and group homes for former psychiatric patients and for unsupported mothers and their children have been supported in Colchester and Nottingham. The University of Kent at Canterbury was given £35,500 towards the cost of a theatre and arts centre at the university, and the universities of Warwick and Wales (Bangor) similar sums for similar projects. At Cambridge grants have been given to continue work on the publication of a new complete edition of the Linear B tablets from Knossos, and to study the demography and social structures of 18th century Britain. The University of York has perhaps the most unusual project of all: £7,850 to study the internal government of British universities.

### More for Research Associations?

At least one of the co-operative industrial research associations will be supported more generously by the Ministry of Technology in the year ahead. It is understood that the ministry has offered the Welding Research Association substantially improved terms of grants, and that the ministry is willing to contribute to the marginal income of the association no less than 150 per cent of what can be raised by means of subscriptions from industrial companies. The standard form of grant entails that the government should match the industrial contribution pound for pound. No doubt the ministry will be quick to inform other research associations that the welding research association is in a special position dictated by the character of its work as a provider of help and advice to a great many industries whose needs cannot always be specified in advance. But there is bound to be a feeling among the research associations that what is good for welding would also be good for others. The way in which the government is encouraging mergers between industrial companies is in any case a good reason for looking again at the financing of the research associations.

### In Charge of Static

A NEW group has been set up by the Institute of Physics and the Physical Society to study static electrification. The new group will encourage study in the generation, dissipation and convection of electric charge on, in and between solids, liquids and gases, and will include both desirable and undesirable electric charges. It is suggested that the group might consider theories of contact electrification, electrostatic charge generation and dissipation, the electrification of liquids during pipeline flow, electrostatic precipitation and coating, and the hazard from static electricity in the textile, chemical, petroleum and photographic industries.

The first chairman of the provisional committee will be Dr. P. S. H. Henry of the Shirley Institute,

and the secretary will be Dr. N. Gibson of Imperial Chemical Industries Dyestuffs Division. There has so far been very little fundamental work on static electrification, and although Dr. Henry believes that the industrial side is the most important (static interferes with production, and can cause fires) he is also hoping to stimulate some fundamental work. Already one three-day conference has been arranged, to be held in London from May 8 to 10, and next year it is likely that regular half-day meetings will be arranged. Although the terms of reference of the group include a variety of disciplines, the problems will apparently be common to all.

### Uproar at Millom

SPRAY steelmaking, a new process developed by the British Iron and Steel Research Association (*Nature*, 212, 331; 1966) seems so far to have created more problems than it has solved. The process, which offers the nearest approach yet to continuous steelmaking at a capital cost said to be less than a third of that of conventional equipment, was developed at the Cumberland works of Millom Hematite Ore and Iron Company. The company, which has run the process so far only on a relatively small scale, is anxious to go ahead with an ambitious plan which would give it a steel capacity of 500,000 tons per year, and continuous casting equipment to make best use of the new process. The plans, which necessarily include gas cleaning equipment, would cost £1 million, and the Iron and Steel Board, which has to approve all expenditure in the industry of more than £100,000, deferred its decision. This was taken as a refusal, for the board had said that it was reluctant to approve the creation of small scale capacity when the trend is towards large scale operation. This week the board gave grudging approval for Millom's plans, adding that it would have prohibited the move if it had had the power to do so.

The deferment of Millom's application had caused uproar in the north-west, aggravated by the success of Lancashire Steel Manufacturing Co., Ltd., in going ahead with a spray steelmaking plant capable of making 50 tons of steel per hour. This is producing steel only three months after building started—remarkable in an industry where new processes characteristically take a long time to catch on. Millom's case was given emotional impact because the town relies almost entirely on the ironworks for employment and without it would be hard pressed to survive. Ironically, since Millom is in a development area, now that it has permission to go ahead the government will make a substantial contribution to the cost of the plant, possibly as much as £450,000.

Despite the bitter arguments, the future for spray steel looks promising. Apart from Lancashire Steel, there are hints that another British company—possibly United Steel—is interested. A Canadian company, Dominion Foundries and Steel, Ltd., has already taken out a licence from BISRA to develop its own spray unit. The company intends to do theoretical research on the process before building a pilot plant. Criticisms in the United States and Canada include the possibility that the reaction chemistry could play havoc with furnace refractory linings (BISRA says that as the reactions do not take place in

contact with the refractory walls, life of the linings should be increased and not diminished) and whether the process is genuinely continuous. If the process has to be stopped to change the composition of the steel produced, much of its advantage would be lost. There is, too, the problem that the process has so far produced only plain carbon steel, and has not been used for alloy steels.

## Animal Sonar

THE international symposium on animal sonar held at Frascati, Italy, under the auspices of the North Atlantic Treaty Organization, the United States Office of Naval Research, and the United States Air Force, brought together for the first time workers in this and related fields from member countries of the North Atlantic Treaty Organization. A feature of the symposium was the opportunity for an exchange of views between biologists, engineers and physicists, and it was so organized that the participants were able to study the main contributions in advance.

It rapidly became clear from the discussions that, although life scientists working on animal sonar had been in contact with sonar engineers over a long period, there had been insufficient exchange of information. Biologists tend to know too little about the advanced physics and systems engineering involved in the work of sonar engineers, while the engineers often lack the biological knowledge to take advantage of the information available about animal sonar. These difficulties have in the past tended to decrease the usefulness of experiments with animals. Such experiments need considerable preparation: the animals must be trained to carry out simple tasks, and the training may take many months. Unless the relevant physical processes are taken into account when the experiment is being planned, the results will be far less useful than they might otherwise have been.

Indeed, despite the extravagant claims of some early workers, animal sonar seems to obey the same laws as do artificial systems. The animal differs from the machine, not in its ability to transcend the laws of physics, but in its ability to adapt, and in the greater storage capacity of its neural system. The animal is also a single integrated system and takes its own decisions. The closest approximately to this aspect of animal sonar that can be achieved with a machine is to link a man to a machine so that he can take decisions. This is the approach used in the portable sonar outfits now issued to some blind persons, and the information obtained as a result of the use of such outfits has given a useful insight into the mode of action of animal sonar. Sonar engineers are probably trying to incorporate some of the animal adaptability into their machines, but they are reluctant to talk about this aspect of their work in public.

The symposium was less successful in its attempt to relate the processing of sonar signals in the animal brain to the systems used in engineering. This is scarcely surprising: neurophysiology is still far from the type of complex model used in systems engineering. Cross-fertilization of ideas will undoubtedly stimulate both sides even in this difficult corner of the field. The symposium seems to have broken the ice separating the disciplines concerned with sonar, and some beneficial effects of the thaw should be evident at the next gathering.

## Ribonuclease Structure—Some Implications

from a Correspondent in Molecular Biology

THE solution of the ribonuclease structure at a resolution of 2 Å by Harker and his collaborators, as reported in *Nature* last week (Kartha *et al.*, *Nature*, **213**, 862; 1967), is clearly an event of unique importance and interest. Of all enzymes, ribonuclease has been the most intensively studied, and its structure is probably that which has been awaited most impatiently by protein chemists, physical chemists and enzymologists alike. The schematic illustration of the chain outline shown in the article gives only a small portion of the information which is expected shortly to emerge, but some interesting conclusions may already be drawn, particularly in connexion with predictions based on chemical evidence.

The active site, as identified by Kartha *et al.*, lies in a deep cleft between two wings of the molecule. There is remarkably good agreement with chemical evidence, due notably to Moore, Stein and co-workers (who also determined the sequence of amino-acids in the molecule). Two histidine residues, his-119 and his-12, were found to be necessary for activity and sterically related; thus, for example, the alkylation of either by a suitable reagent was prevented by the alkylation of its partner. These residues are indeed seen to flank the active centre cleft. Another residue which was unambiguously shown by Hirs in 1962 to be required for activity is lys-41, which appears at the third surface of the cleft opposite the two histidines. There is also some evidence for the involvement of lys-7 and indeed it has been shown that lys-7 and lys-41 can be joined by a bifunctional cross-linking reagent. With a minimum of hindsight it can be seen that other more equivocal identifications of active residues in the literature now appear to be wrong. Suggested mechanisms, of which a number have been put forward, will have to await critical examination until electron density maps of the enzyme with a bound substrate analogue have been obtained.

It is interesting to note that the segment corresponding to the *S*-peptide of Richards stands away from the molecule, almost over the cleft. This peptide (residues 1–20) can be split off by hydrolysis of a single peptide link with subtilisin. It will recombine non-covalently with the remainder of the enzyme molecule (*S*-protein) to give an active product. It was shown by Anfinsen and co-workers that residues 16–20 are in fact largely dispensable for binding and activity, but that 14 and 15 are required for proper binding. It is gratifying that residues 16–20 in the model appear to form a loop barely in contact with any other part of the protein, whereas in the region of residues 14 and 15, non-covalent interactions are likely.

The  $\alpha$ -helix content of ribonuclease is low, 17 per cent being apparently an upper limit. This agrees well enough with optical rotatory dispersion measurements, which give values around 15 per cent. No  $\beta$ -conformation is present.

The appearance of the ribonuclease structure necessarily represents, among other more important consequences, a day of reckoning for those bold enough to have offered three-dimensional structures based only on indirect evidence. Such structures do not appear to have fared well. The most recent, by Hammes and Scheraga, has features in common with reality (apart

from the constraints provided by the disulphide bridges) only to the extent that it incorporates the correctly identified residues mentioned above juxtaposed in the active centre. For the rest, the non-covalent interactions deduced by Scheraga and co-workers are evidently almost wholly specious. Earlier models, by Saroff and by Scheraga, are as different from the above model as they are from the actual structure. At the present stage it therefore appears that the indirect approach to the construction of three-dimensional protein structures is of dubious value.

The appearance of more complete structural data will offer the possibility of interpreting the mechanism of nucleolytic hydrolysis, and will now be awaited with the greatest interest.

## Momentum Dependent Interactions

### from a Correspondent in High-energy Physics

IN a recent experiment at the Cornell 2 GeV synchrotron, K. Kerkelman *et al.* (*Physics Letters*, **24B**, 165; 1967) have measured the momentum dependence of the magnetic dipole transition between a proton and the positively charged  $N^*$  resonance at 1,230 MeV.

The inelastic cross-sections for the processes in which an electron striking a proton produce in the final state an electron together with either a proton and a neutral pion or a neutron and a positively charged pion show a marked enhancement when the effective mass of the final nucleon and pion system is near 1,200 MeV. This effect is usually interpreted as a first order electromagnetic process in which the scattered electron emits a virtual photon—one for which the effective mass is not zero—which in turn excites the proton into a state with mass 1,200 MeV. A final pion and nucleon are then produced by the (very fast) strong decay of this  $N^*$  resonance—or particle as it is frequently called. On this interpretation of the state as a particle with isotopic spin  $3/2$ , positive parity relative to the nucleon and spin  $3/2$ , the transition from the nucleon induced by the virtual photon can be shown by general covariance and angular momentum properties to be of only three possible types. These are a magnetic dipole ( $M1$ ), an electric quadrupole ( $E2$ ) and a Coulomb octupole ( $C2$ ) transition, each of which is measured in terms of a corresponding form factor depending only on the momentum transfer (the effective invariant mass of the virtual photon).

If the analysis in terms of a virtual photon is valid, then these form factors have already been measured for zero momentum transfer by experiments in which the  $N^*$  state is excited by a real photon (Gourdin, M., and Salin, P. H., *Nuovo Cimento*, **27**, 193; 1963). Thus it is known that the form factor describing the  $M1$  transition has a value at zero momentum transfer of  $3.00 \pm 0.01$  in units of nuclear Bohr magnetons and that the other two transitions are much smaller (less than 5 per cent). In the electro-production experiment the analysis is therefore based on the assumption that only the  $M1$  transition contributes—a fair assumption for this first experiment. This simplification makes it possible in principle to measure the  $M1$  transition form factor  $G_M^*(k^2)$  by the standard techniques of observing only the scattered electron, provided that the dominant contribution is known to be from the  $N^*$

and not from non-resonant background effects. The technical advance which has made this experiment possible is that events have been selected in which a final proton and neutral pion are detected in coincidence. Since the photoproduction results indicate that this final state (in contrast with the neutron-positive pion state) is predominantly resonant, the background is largely eliminated.

The results obtained over a range of momentum transfers up to 8 (GeV)<sup>2</sup> extrapolate neatly back to the value at zero momentum transfer measured in the photoproduction experiments, and thus confirm the validity of the model assumed. Furthermore, the momentum dependence is roughly in agreement with the predictions of both the dispersion theory and the relativistic symmetry schemes for the strong interactions which are presumed to be the source of this effect, although detailed comparison requires much improved experiments.

This experiment surely marks a new era of sophistication in the use of electron machines. The new synchrotrons in Germany (DESY) and England (NINA) are starting operation without any substantial energy advantage over earlier machines. Crude elastic electron scattering experiments can hardly justify extensive running time, and inelastic experiments, particularly of the coincidence and polarization types, must figure largely in their future programmes.

## Egon Bretscher Retires

THE Atomic Energy Research Establishment at Harwell, now 21 years old, is branching out into new fields with the setting up of centres for ceramics and materials testing. It remains, however, a place with powerful associations for physicists, and two of them have recently been writing of the retirement of Dr. Egon Bretscher, head of the Nuclear Physics Division since 1948, who had been associated with work on atomic energy since the early days of the war. After graduating as a chemist in 1927, Bretscher had moved to Cambridge, where he collaborated with Feather on the problem of uranium  $Z$  when, according to Feather, "progress depended essentially on the trustworthiness of Bretscher's chemical preparations: time has shown that they were impeccable". This was followed by neutron bombardment with particles from the one million volt accelerator, and towards the end of 1938 the group was making preparations to study the X-radiation of the supposed transuranic elements—those which, a few months later, were shown by Hahn and Strassman to be radioactive isotopes of elements with smaller atomic number.

A. P. French explains how Bretscher turned from the radiochemistry of uranium to the measurement of fission cross-sections for fast neutrons using neutrons from the D+D reaction. One of Bretscher's innovations at this point, in 1942, was to devise a way of extending the technique of measurement with a homogeneous ionization chamber so as to measure neutron flux in the presence of a strong gamma-ray background as with neutrons from the  $^{12}\text{C}+\text{D}$  reaction. This work was helped along by the possession in Cambridge of 2 g of fully deuterated paraffin wax, prepared a few years earlier at the heavy water plant in Norway. French says that this was used to line a chamber that was filled with deuterio-ethylene and used differ-

entially with an otherwise identical chamber lined with ordinary paraffin wax and filled with ordinary ethylene—a very clever scheme for automatically balancing out the ionization current due to gamma rays while leaving a calculable effect due to neutrons.

In 1944 Bretscher and many of his colleagues moved to Los Alamos, and French notes that even then thinking had moved beyond the fission bomb to the possibility of making a hydrogen bomb. But experimental information on the relevant reactions involving deuterium and tritium was sadly lacking. As French points out, “the  $D + D$  reaction had never been followed down to thermonuclear energies of the order of 10 keV, and the reaction of deuterium with tritium was mostly a big question mark, though there were hints and speculations of a prodigious cross-section”.

Bretscher directed the design of a low voltage accelerator to record protons from these reactions between like nuclei. Some time in 1945, “the world supply of pile-produced tritium gas—a whole cubic centimetre of it, many times more costly than plutonium, weight for weight—was delivered to us, and with this we were to make our measurements. Bretscher himself undertook the nerve-racking task of breaking the vial of tritium inside a gas-transfer system. Late one night, shortly afterwards, the crucial moment came. The gas supply to the ion source was switched from deuterium to tritium. Instead of occasional pulses on the oscilloscope, there appeared an absolute hail-storm. The implications were frightening and as soon as we had convinced ourselves that the result was genuine we went home in a mood that was a strange blend of excitement and awe.

“Over the next few months the measurements were refined and extended, with the help of a couple more consignments of tritium. Everything confirmed the first indications; the  $T + D$  reaction had a monstrously large yield (of the order of fifty times greater than for  $D + D$ ) at fission-bomb temperatures. The theoreticians seized on these results, and it seemed obvious at the time that the super-bomb would consist of a great mass of liquid deuterium set off by a fission bomb fuse and a tritium/deuterium detonator. But practical realization of such a design was certainly not going to happen soon, especially as the ending of the war brought about a general lessening of urgency.”

## Parliament in Britain

In a written answer in the House of Commons on March 1, the Minister of State for Education and Science, Mr. G. Roberts, stated that studentships were only awarded by the Science Research Council and the Social Science Research Council to nominees of university departments. In 1966, the Social Science Research Council received 429 nominations, and 43 were not offered awards. The Science Research Council received 2,567 nominations in 1964, and 60 were not offered awards; for 1965, the figures were 2,928 and 143; and for 1966, 3,096 and 321.

On March 2, also in a written answer, Mr. Roberts gave figures for the average expenditure per full-time student of the universities for the academic year 1964-65. The figures vary from £2,377 (Essex), £1,268 (London), £1,125 (East Anglia), £1,121 (Reading), £1,092 (Manchester Institute of Science and Technology) to £695 (St. Andrews), £690 (Durham), £612 (Strathclyde), £580 (Hull), £563 (Exeter), and £537 (St. David's College, Lampeter). The figures for Cambridge (£805) and Oxford (£781) are not directly comparable as they exclude all expenditure by the Colleges.

In giving an analysis of the origin by country of the 2,686 Commonwealth students in Britain who are supported by British public funds, the Parliamentary Secretary to the Ministry of Overseas Development, Mr. A. E. Oram, in a written answer in the House of Commons on March 2, stated that the average cost of a student from the beginning to the end of his course and allowing for passage costs, etc., was about £2,425. This did not include the hidden subsidy represented by the uneconomic fees charged by institutions of higher education.

In a written answer in the House of Commons on February 28 the Minister of Technology, Mr. A. W. Benn, gave a long summary of the action taken to implement the fourteen recommendations of the Fielden Committee on Engineering Design which reported in June 1963. A series of regional conferences on engineering design were arranged during 1964 by the Federation of British Industries and the Department of Scientific and Industrial Research. The Ministry of Technology works closely with the Council of Engineering Institutions in its efforts to raise the status of the engineering profession as a whole, and after 1973 the academic standard required for the professional qualifications of “Chartered Engineers” will be of degree standard. The Science Research Council has continued to award grants for studies of the design process. Ways of introducing elements of engineering design into certain National Certificate and Diploma courses in engineering are being considered by the Department of Education and Science, while the Engineering Industry Training Board has set up a Technologist Training Policy Committee to prepare a manual on training professional engineers in industry. The first of the institutes recommended by the report has been established at the National Engineering Laboratory at East Kilbride. In addition, he added that the Ministry of Technology and the Science Research Council had placed contracts to further the development of computer-aided design.

## University News: Aston in Birmingham

PROFESSOR D. F. LAWREN, at present professor of mathematics in the University of Canterbury, New Zealand, has been appointed to the chair of mathematical physics in the Department of Mathematics.

## Bradford

PROFESSOR A. RAHMAN, scientist in charge of the Survey and Planning of the Scientific Research Unit of the Council of Scientific and Industrial Research, India, and in charge of the International Scientific Collaboration Bureau, has been invited to a visiting chair in science planning and sociology of science for one year.

## Nottingham

PROFESSOR H. J. KING, at present professor of applied mineral sciences in the University of Leeds, has been appointed professor and head of the Department of Mining Engineering in succession to Professor F. B. Hinsley.

## Reading

PROFESSOR J. WRIGLEY has been appointed to the joint post of professor of curriculum research and development in the university, and director of studies and research adviser to the Schools Council. Dr. J. B. Adams and Mr. A. E. Milward have been co-opted to membership of the Council of the University. Mr. Milward has been chairman of the Friends of the University since 1956, and Dr. Adams is member for research of the U.K.A.E.A.

## Appointments

DR. T. M. SUGDEN has been appointed director of the Thornton Research Centre of "Shell" Research, Ltd., near Chester. Dr. Sugden was reader in physical chemistry at the University of Cambridge before joining Shell in 1964, and is best known for his work on combustion, particularly in the detection of traces of metals by flame photometry.

MR. P. H. STEPHENSON, formerly chief mechanical engineer of the Pye Group of Companies, has been appointed director of the Institute of Advanced Machine Tool and Control Technology at East Kilbride, near Glasgow. The institute is the first to be established following the recommendation of the Feilden Committee on engineering design. Mr. Stephenson has also been appointed a professor of the University of Strathclyde.

DR. B. G. F. WEITZ has been appointed director of the National Institute for Research in Dairying in succession to Sir Ronald Baskett.

## Announcements

THE James Clayton prize for 1966 has been awarded by the Institution of Mechanical Engineers to Dr. S. G. Hooker and Mr. A. A. Lombard for their contribution to the design and development of aero-engines leading to great advances in aerial transport, and particularly for their work in the field of vertical lift for take-off and landing.

THE International Journal of Cancer wishes to publish a collection of brief reports of the occurrence of Burkitt's lymphoma outside the African region, and the editor would be interested to receive reports from workers in this field. Further information can be obtained from Professor E. A. Saxén, Editor in Chief, International Journal of Cancer, 111 Department of Pathology, University of Helsinki, Helsinki 25.

THE Summer Courses of the International School of Physics "Enrico Fermi" are to be held this year at Varenna. The first course, which is during June 26–

July 15, is entitled "Nuclear Structure and Nuclear Reactions"; the second course, which is during July 17–29, is entitled "Selected Topics in Particle Physics"; and the third course, which is during July 31–August 19, is entitled "Quantum Optics". Further information concerning all three courses can be obtained from the Società Italiana di Fisica, Via Irnerio, 46—Bologna.

A THREE weeks course on the "Application of the Electron Microscope to Problems in Molecular Biology", sponsored by the European Molecular Biology Organization, will be given in the Institut de Biologie Moléculaire in Geneva during September 4–23. The course will stress specimen preparation and examination techniques and will be designed for participants at the post-doctoral or advanced Ph.D. student level with a good background in some branch of molecular biology. Applications should be sent before June 1, and further information can be obtained from either Lucien G. Caro, Biology Division, Oak Ridge National Laboratory, P.O. Box Y, Oak Ridge, Tennessee, or Edouard Kellenberger, Laboratoire de Biophysique, Institut de Biologie Moléculaire, Université de Genève, 24 quai de l'Ecole-de-Médecine, 1211 Genève, 4.

A SYMPOSIUM on the "Systematics of Cultivated Plants and Domesticated Animals", organized by the Systematics Association, will be held at the Dunfermline College of Physical Education in Edinburgh during April 12–13. Further information can be obtained from Dr. Patricia J. Watson, Scottish Plant Breeding Station, Pentlandsfield, Roslin, Midlothian.

ERRATUM. In the article entitled "Evidence for a New Mechanism of Respiratory Stimulation and Proton Ejection in Ehrlich Ascites Tumour Cells dependent on Potassium Ions" by Edwin E. Gordon, Kerstin Nordenbrand and Lars Ernster (*Nature*, 213, 82; 1967), the concentrations of the reagents specified in the caption to Fig. 1 were wrongly printed as in moles/l. They should, of course, have been in mmoles/l. In the legend to Table 1, where the composition of media for depleting cells of potassium ions were specified, the sodium concentration should be 1.78 mmoles/l. In the lithium medium, the concentration of magnesium should have been given as 1.5 mmoles/l. (not 1–5 mmoles/l.), and the other ingredients should have been 1.5 mmoles/l. of magnesium, 154 mmoles/l. of chloride, 1.5 mmoles/l. of sulphate, 12 mmoles/l. of phosphate. The choline medium had 154 mmoles/l. of choline, 1.5 mmoles/l. of magnesium, 12 mmoles/l. of *tris*, 166 mmoles/l. of chloride, and 1.5 mmoles/l. of sulphate.

The following corrections should also be made. Page 83, left-hand column, line 32, should read: There was release of inhibition of respiration and inhibition of extrusion of hydrogen ions induced by oligomycin on addition of valinomycin. Last sentence, left-hand column, p. 83, should read: Further addition of potassium ions to the cells depleted of this ion resulted in a significant effect on both parameters for the cells depleted in the media containing either sodium or lithium ions. The effect . . . The legend to Fig. 2 should read: Release of respiration and proton extrusion inhibited by oligomycin in cells depleted of potassium ions. Page 84, left-hand column, line 23, should read: The release of respiratory inhibition induced with oligomycin by potassium ions plus valinomycin was similar to the release effected by dinitrophenol, except that the release by dinitrophenol was not dependent on the presence of potassium ions. The authors are indebted to Dr. J. C. MacDonald of the Prairie Regional Laboratory, Saskatoon, Saskatchewan, Canada, for providing the valinomycin.

ERRATUM. In a note entitled "British Science Spending" in News and Views (*Nature*, 213, 749; 1967), the second of the four research councils listed should have read Natural Environment Research Council and not National Engineering Research Council.

# Education in East Germany

by

NIGEL HAWKES

*Jena, February*

MR. McNAMARA thinks that Europe is educationally backward, and makes no bones about saying so (*Nature*, 213, 851 and 853; 1967). Certainly there are few European countries which can rival the United States in terms of the sheer quantity of education which it supports. There is, however, one country at least in Europe which claims to match America's commitment to education. Twenty per cent of its GNP is spent on education, and one-third of its students continue education beyond the age of 18. The education system has a distinctly technological bias—all of which would doubtless gladden Mr. McNamara's heart, if East Germany were not part of the communist bloc.

Since the war East Germans have shown a compulsive desire to eliminate all traces of the old Germany. West Berlin, like most cities, is a pleasing mixture of old and new, and has a traffic problem; East Berlin, on the other hand, is a city of sweeping boulevards flanked by ten-storey blocks of workers' flats built with wonderful thoroughness but a sorry sense of design. Education has also been completely reconstructed, in a way which illustrates that East Germans are pragmatists as well as socialists. What follows is based on a description of the East German system supplied by the director and assistant directors of the apprentice school at Jena, one of the largest in the country. While the figures are impossible to substantiate—if they are all true it is difficult to see where supplies of unskilled labour come from—there is no reason to doubt the general structure, although it may not be in general operation everywhere in the country.

The backbone of the structure is the system of "polytechnic" schools. Children enter them at the age of 6, and most stay until the age of 16. These schools give a general education, with a powerful push towards vocational training; in the last two or three years children spend one day in each week in practical training in factories, in a kind of inverted version of British "day release". The aim is for all children to stay at school until the age of 16, but it is admitted that at the moment about 10 per cent leave at the age of 14. Russian is taught from the age of 11, and English—as an option—from the age of 13.

At 16, the student has three choices. The commonest course is to enter an apprenticeship, which lasts two or three years, and leads to a nationally recognized certificate. Some 40 to 50 per cent of school leavers do this, East Germans claim. Training during apprenticeship is free, and a nominal allowance of 120 marks (about £10) a month is paid. When the apprenticeship is completed, an employment agreement is signed; most apprentices at the Jena apprentice school stay in Jena to work for Carl Zeiss "as a matter of course". The whole cost of the course, and the teachers, is paid by the state, and there are apparently more applicants than places.

Two other courses are open to the school leaver, both leading to higher education in universities and high schools. About 20 per cent of the 16 year olds go to extended polytechnics until the age of 18, when the

Apart from the special schools, the East German education structure shows no division until the age of 16, when transfer takes place. In Britain the Plowden report, devoting five pages to a discussion of the age of transfer, decided that 12 was the ideal age.

qualifying examination for university entrance—the "Abitur"—is taken. The other possibility is to take a combined "Abitur" and vocational training course, which takes three years to complete. At the end of the course the students are qualified either to enter university or high school, or to take up the vocation they have studied.

So far the system seems to conform with socialist principles. But there are other, newer schools which are by no means as egalitarian, and are clearly designed to cultivate an élite. These are the special schools, which only a tiny minority—about 2 per cent—of the population attend. The special schools cover subjects such as technology, sport, fine art, and music, and the children selected for them start at the age of 12 and continue until they are 18. The best pupils in the polytechnic schools are selected for special schools on the basis of reports from their teachers, and it is claimed that the method of selection is so good that only 2-3 per cent of those selected drop out before the age of 18. It is not possible for able pupils passed over at the age of 12 to enter the special schools at a later stage, so that the schools represent a complete separation of a small section of the population from the rest. The products of the special schools in technology are intended to be middle or top managers in industry, or to take up jobs as representatives overseas. In addition, although, of course, the East Germans are

not explicit about this, special schools offer very good opportunities of recruitment to the Communist Party, or at least of obtaining loyalty to the party line. This is particularly important for those who are allowed to travel overseas, either as sales or service engineers, or even as sportsmen.

Great stress is laid on group activities in all East German schools, and particularly in the special schools. The groups are organized by the teachers, assisted by youth groups such as the Youth Pioneers, and the aim is to promote "collective as well as individual achievement". To judge from the posters which are displayed by the youth groups in the apprentice school at Jena, political activities go at least as far as condemning American activity in Vietnam, and declaring support for the socialist state, if no further. The posters seem no more offensively propagandist than any that might be seen in Trafalgar Square, but their unanimity is depressing. The apprentices themselves—half are girls—seem very young by comparison with western 15 year olds, but a down to earth style of dress and absence of cosmetics have a lot to do with this.

Central control combined with a belief in education does provide one benefit which hard-pressed British teachers would welcome—East German teachers are paid more than their counterparts in industry. Their advantage is derived from an arrangement which provides for them to pay tax on only 70 per cent of their income. This fringe benefit, it is explained, is not a capitalist blunt instrument for persuading people to become teachers, but is intended to allow teachers to buy the books and literature they need. Whatever the reason, pupil-teacher ratios (not to be confused with the actual numbers in each class, which are slightly higher because not all teachers are working all the time) seem much the same as in Britain, 28:1 in the polytechnics, and 25:1 elsewhere. Teachers work a 45 hour week, and teach 24 lessons (each of 45 minutes) each week; the rest of the time is for preparation. This suggests that some of the

classes must be very large indeed, although the absence of separation into primary and secondary schools may allow the British primary school crush to be avoided.

To recruit people to important jobs in a country where salaries are rigidly controlled and do not respond to market forces obviously calls for efficient forward planning, and vocational guidance which falls just short of compulsion. Children decide on their professions at the age of 15, but vocational guidance begins with "toy construction sets" at the age of 11. Direct guidance begins at the age of 13, when "factory day release" begins. The East Germans admit that one advantage of the polytechnics is that "children become acquainted with production very early". They are taught to understand the country's needs, and apparently "conflict is rare". Changing from one form of training to another is also rare, and outright failure, the Germans believe, "belongs to the past". Whether this system works better than the unpredictable surges of the free economy is doubtful, but certainly it relies very heavily on accurate central planning, and risks being overtaken by events. There are, for instance, very few computers, and even fewer systems analysts, in East Germany.

East Germany suffers from a brain drain, though the flow has been staunch since the building of the Berlin Wall. It is a migration in two directions, as the very best students are often rewarded by being allowed to go to the Soviet Union to further their education. This the East Germans do not mind, for they regard it as a compliment to their educational system, in much the same way as Mr. Quintin Hogg applauds the migration of British scientists to the United States. There is, in addition, the drain to the West, from which, surprisingly, the East Germans wring some wry humour. Their favourite story, doubtless apocryphal, concerns Dr. Adenauer, the former West German Chancellor. Asked by a visitor where the West German universities were, he is alleged to have replied, "Our universities? Oh, they are all in the Eastern zone".

## Restoring Atmospherically Degraded Images

by

S. P. MORGAN

Bell Telephone Laboratories,  
Murray Hill,  
New Jersey,  
U.S.A.

How is it possible to extract the most information from optical images degraded by the passage of light through the atmosphere? This was the subject of the Woods Hole Summer Study on the Restoration of Atmospherically Degraded Images held at the Summer Studies Centre of the National Academy of Sciences between June 27 and July 22, 1966. The director of the study has singled out some of the principal themes and conclusions.

It was pointed out in Newton's *Opticks* (Book I, Part I, Prop. VIII, Prob. II; 4th ed., 1730) that even if "the Theory of making Telescopes could at length be fully brought into Practice, yet there would be certain Bounds beyond which Telescopes could not perform. . . . Long Telescopes may cause Objects to appear brighter and larger than short ones can do, but they cannot be so formed as to take away that confusion of the Rays which arises from the Tremors of the Atmosphere." For example, the diffraction limit of a 48-in. telescope is 0.1 sec of arc, but "seeing" effects limit the actual resolution to several tenths of a second. A recent study sponsored by the United States National Academy of Sciences undertook to investigate how far such non-Newtonian devices as electronic computers and lasers may be able to circumvent

the effects of atmospheric turbulence on the formation of optical images.

The Summer Study did not consider techniques of image enhancement that depend only on some form of contrast amplification to make a photographic image more open to interpretation, for it was assumed from the start that one would be able to perform more sophisticated operations on a recorded pattern of light intensity with the object of undoing degradations and of restoring, as nearly as possible, the image that would have been recorded in the absence of degradations. Among the resources of modern technology which may contribute to this end are high speed digital computers with large memories, powerful laser sources of coherent radiation, and electro-optical image sensor techniques which are fast

enough to "freeze" image motion due to atmospheric turbulence.

The attention of the Summer Study was focused on a relatively restricted problem—that of the restoration of images of objects which subtend small angles and which are viewed against a dark uncluttered background and which are photographed from the ground looking up. This problem arises, of course, in photographic natural or man-made objects in space through a ground-based telescope. It is perhaps the simplest real problem in image restoration, because of the limited number of resolution elements in a typical image; but it has the merit of being both intrinsically important and also a stepping-stone to more difficult problems. At the Summer Study we did not consider such sources of image degradation as imperfect optical systems or motion due to tracking errors, even though it is well known that many of the restoration techniques that are useful for atmospheric turbulence can correct for these factors as well.

Three principal lines of investigation were pursued at Woods Hole. Briefly, these may be called passive image processing, wavefront-reconstruction imaging and pre-detection image processing.

In passive image processing, one attempts to answer the question, "Given a conventionally formed and atmospherically degraded image, what can be done to make its information content more intelligible?" One way of looking at the problem is as follows.

Because the effect of atmospheric turbulence is, in general, to reduce the amplitudes of the higher spatial frequency components of an image, the objective is to restore these components to their proper values. During very short exposures, the high spatial frequencies are not attenuated as much as during long exposures, but they are provided with instantaneous phase shifts which must be compensated for. The long-exposure transfer function of the atmosphere is fairly well known, but for short exposures it is an important problem to obtain either exact or statistical knowledge of the instantaneous transfer function, so as to correct for it. Another question which has not yet been adequately studied concerns the restoration of extended images, where the effects of turbulence are not invariant over the image—when the object does not lie in a single isoplanatic region.

The most impressive examples of passive image restoration which were shown at Woods Hole were due to J. L. Harris (Visibility Laboratory, Scripps Institution of Oceanography, University of California, San Diego). Harris has restored both long and short exposure images of simple objects such as the characters "S" and "5" which have been degraded by heat-induced turbulence in the laboratory, by using digital Fourier techniques on a Control Data Corporation 3600 digital computer (*J. Opt. Soc. America*, **56**, 569; 1966). A typical restoration may involve  $60 \times 60$  image points, although larger formats are possible. Work at the Visibility Laboratory is being continued actively. In particular, Harris is making an experimental study of the statistics of the optical transfer function of a turbulent medium.

Digital techniques are extremely flexible and convenient for image processing research, but the time required for the computations depends critically on the number of points to be processed. An alternative method of spatial frequency filtering, which can accommodate very rapid processing rates, is provided by an optical analogue system (Cutrona, L. J., *I.E.E.E. Spectrum*, **1**, 10, 101; 1964). The basic principle of an optical analogue system is that if a lens is placed a focal distance away from a transparency, the light at the focal distance away from the lens on its output side will be distributed according to the two-dimensional spectral analysis of the object. A spatial frequency filter can be provided by placing at the output focus a transparency whose transmittance varies in any desired manner, and the inverse transform of the filtered image may then be produced

by a second lens another focal distance away. Some preliminary examples of photographic images degraded by turbulence generated in the laboratory and restored by optical analogue filtering were shown by Dr. G. O. Reynolds (Technical Operations, Inc., Burlington, Massachusetts).

Against the operating speed and conceptual simplicity of an optical analogue processing system must be balanced a number of practical difficulties. Among these are diffraction noise due to dust and lens imperfections, the problem of achieving linearity in photographic response—in principle, digital processing can correct for nonlinearity, whereas optical processing cannot—and the problem of dynamic range.

It is apparent that in several ways digital and analogue image processing techniques are complementary to each other. One might therefore imagine an ultimate system which would combine the best features of both in an on-line operation.

An important limitation of passive image restoration techniques is that one does not usually know the optical transfer function of the randomly varying atmosphere at the instant the image is recorded. An active technique recently proposed by Dr. J. W. Goodman and his colleagues (Stanford Electronics Laboratories, Stanford University, California) uses a laser beam to illuminate the object and essentially to record the properties of the atmosphere at the same time. This technique, which is based on the principles of holography, is potentially immune to many of the atmospheric effects that degrade the quality of directly formed images.

The Goodman wavefront reconstruction technique records on a photographic transparency the interference pattern between laser light reflected from the desired object and a coherent reference source near the object. When the transparency is regarded as a hologram, illuminated by a collimated coherent beam and followed by a converging lens, the two first-order diffraction patterns on either side of the lens axis provide a pair of twin images of the original object. It can be shown that if the light from the object and the light from the coherent reference source undergo arbitrary but nearly identical phase shifts in a random transmission medium, the reconstructed images will to a first approximation be unaffected by the presence of the random medium. The closer the phase-perturbing region is to the receiving aperture, the less will be the effect on the reconstructed images. Nearby phase perturbations, on the other hand, are exactly those which degrade the quality of a conventionally formed image most severely.

Dr. Goodman and his colleagues have restored in the laboratory images degraded by a piece of shower glass in front of the receiving aperture (*App. Phys. Lett.*, **8**, 311; 1966). They have also shown that wavefront reconstruction imaging is possible when the coherent reference source is a specular point on the object itself. For a co-operative object, of course, the reference source is most easily provided by a corner reflector. Laser technology would at present appear to provide power levels and coherence lengths which are adequate for imaging low-altitude objects in space, and work is continuing at Stanford.

Although most of the attention at Woods Hole was directed toward the methods just discussed, two systems were considered which in some sense use electronic means to improve the quality of an image before it is recorded.

The first system, due to Dr. R. L. Gregory (Psychological Laboratory, University of Cambridge), involves a technique for selecting automatically those instants when the major features of an image are in their statistically correct positions, as determined from a previously taken long-exposure negative, and maximally sharp. It then builds up a single picture from a series of very short

(continued on page 969)

# The Problem of Quasars

by

F. G. SMITH

University of Manchester  
Nuffield Radio Astronomy Laboratories,  
Jodrell Bank, Macclesfield, Cheshire

Quasars create more problems than they solve. How can such small star-like objects emit such large quantities of energy? Why do their spectra show such anomalously high red-shifts? How are they related to radiosources and visible stars?

THE discrete sources of cosmic radio emission were once known as "radio stars", by analogy with the discrete sources of light which are scattered similarly over the sky. Identifications of many radio sources with visible galaxies soon ended this terminology, and ended also any thought that the radio sources could be associated with star-like bodies. As more detailed maps became available of the wide extent of radio emission outside the visible parts of these radio galaxies, so it appeared more obvious that radio sources were large clouds of electrons with associated magnetic fields, very distant, and not at all like stars. Following this simple view, the cosmological interpretation of the number-intensity counts gave a clear rejection of the steady-state theory, and the first details of the development of radio galaxies through the early history of the universe.

Only one puzzling observation remained unaccounted for. The angular diameters of radio sources can be measured by the use of interferometers with sufficiently long baseline, and it is fairly easy to achieve this for most radio galaxies. Many of the radio sources in the 3C Cambridge catalogue were found in this way to have angular diameters of the order of 1 minute of arc. In 1960 an attempt at Jodrell Bank to resolve the smallest angular diameters by extending the measurement to a baseline of 32,000 wavelengths was surprisingly unsuccessful; some radio sources were apparently less than 3 arc sec across. It was known that three of these radio sources were coincident with three bright blue star-like objects, but it was not until accurate positions were available

from a combination of measurements at Cambridge and Owens Valley, California, that the coincidence was taken seriously. Sandage then measured the spectrum of one of them, 3C 48, and found unusual and unidentified broad emission lines.

Then came, in 1963, the identification of 3C 273 with another "star", even brighter, with a position determined to 1 arc sec by the observation of a lunar occultation at Parkes, Australia. This "star" had a wispy cloud extending 19 arc secs from it, and a part of the radio source was located in the wisp.

Fig. 1. Shape of the radiosource 3C 47 determined by the one-mile interferometer at the Mullard Radio Astronomy Observatory, Cambridge, at a wavelength of 21 cm. The optical quasi-stellar object is marked by a cross. The radio source consists of two components 62 sec of arc apart set nearly symmetrically either side of the optical object with flux densities in the ratio of 1.8 : 1. The optical object has a red-shift of  $\Delta\lambda/\lambda = 0.452$ .

Fig. 2. The variation with apparent intensity of the numbers of celestial objects of a particular type can indicate their distribution throughout the Universe. The slope of  $\log N$  ( $N$ =number) against  $\log S$  ( $S$ =flux density) for radio sources away from the galactic equator, as measured at Cambridge, is  $-1.85$ , which is inconsistent with any model of equally luminous and uniformly distributed objects. In 1966 Véron (*Nature*, 211, 724) classified the extragalactic radio sources into radio galaxies and possible radio galaxies, quasars and possible quasars, and radio sources for which there is no visible star (empty fields) and radio sources the identification of which with a visible object is uncertain. The slopes of  $\log N$  against  $\log S$  for the different classes vary, as shown in the figure. The slope of the graph for the quasars is highest ( $-2.2$ ).  $\times$ , All extragalactic radio sources in the Revised 3C Catalogue;  $\circ$ , radio galaxies;  $\Delta$ , quasars;  $+$ , the quasars, the empty fields and the non-identified sources

The optical spectra of the three stars had shown unidentifiable emission lines and an exceptionally bright blue continuum. In 3C 273 the emission lines were identified by Schmidt as the Balmer lines from hydrogen,

shifted to the red by a factor 1.158 ( $z=0.158$ ). The spectra of the other three were re-examined and clearly fitted the same pattern, but with different values of  $z$ . About 100 of these quasi-stellar objects, the quasars, have now been identified, and it seems likely that a third of the 10,000 catalogued radio sources may turn out to be quasars. There are probably many more visible, but radio-quiet, quasi-stellar objects. Observational evidence is mounting rapidly but we still do not know for certain what they are, where they are, how they were made, or how long they last.

If the red-shift is indeed a Doppler shift conforming to Hubble's Law, the quasars are the most distant objects known. Several values of the red-shift parameter  $z$  greater than 2 are already known, while radio galaxies have values only up to 0.46. The emitted power is then calculable from the distance and the observed intensity over the radio spectrum; it amounts to  $2 \times 10^{47}$  ergs sec<sup>-1</sup> for 3C 273. A life-time of  $10^5$  years is plausibly assumed, and the total energy emitted is reckoned to exceed  $10^{50}$  ergs. This energy could be obtained by converting into helium a mass of hydrogen equal to  $10^9$  solar masses. There are only about  $10^{11}$  stars in a whole galaxy and even if we involve a whole galaxy it is difficult to find a sufficiently efficient physical process of energy conversion. So much energy can only have come from gravitational potential energy, or from a nuclear process, or a combination of both. But the explanation would be easier if the energy were less, which means either a shorter life or a smaller distance. Both are possible. There has been more discussion about distance, so we examine this first.

Fig. 3. A plot of the red-shift as a percentage of the original wavelength against the velocity of the source as a percentage of light (after J. L. Greenstein). The top of the curve is uncertain because as yet the large scale geometry of the Universe is unknown. The arrow marks the point of the most distant radiogalaxy and above this all points are for quasars. (1) 3C 273; (2) most distant (measured) ordinary galaxy; (3) 3C 48; (4) most distant radiogalaxy; (5) 3C 254; (6) 3C 287; (7) 3C 298; (8) 3C 454; (9) 3C 9; (10) 1116 + 12.

There are three disturbing aspects of the observed red-shifts which suggest that Hubble's Law may not be directly applicable to quasars. First, there is a strange distribution of red-shifts among the quasars. The high value of  $z=2.02$  appeared among the first ten to be measured; with 100 the largest value is still only 2.12, and there is a relative paucity of  $z$  values between 1 and

2. Second, the absorption lines now being found in the optical spectra do not have the same  $z$  values as do the emission lines. The third difficulty concerns the expected absorption of light on the short wavelength side of the red-shifted Lyman alpha line of hydrogen. This absorption is an extremely sensitive test of the presence of neutral hydrogen between the source and the observer. No absorption is seen and it is necessary either to assume that there is virtually no hydrogen or that the red-shift does not correspond to the expansion of the universe. Both represent distasteful complications of cosmology.

Could part of the red-shift be gravitational? The difficulty here is to form the sharp optical emission lines in regions where both the gravitational potential and its gradient are low enough, and where the potential is the same for all emission lines. This cannot occur for a single massive body, as was shown by Greenstein and Schmidt<sup>1</sup>. It could only occur if the light were emitted from inside a massive body; Hoyle and Burbidge<sup>2</sup> suggest that the optical lines come from a concentration of gas at the centre of a tight cluster of separate massive bodies. The absorption lines would then occur in cooler gas farther from the centre.

Gravitational red-shift is seen to be a very open question, but it does not follow that the quasars can be very close to us. They are distributed reasonably isotropically around us, and the only heavenly bodies of which the same can be said are the distant extragalactic nebulae. If they are local, and the red-shift is a Doppler effect, then they are receding from a point near us where the energy contained within all of them was once concentrated. No other such points are known in the universe because we do not see the very bright blue-shifted quasars which would emerge from them. At the very least, the distance of most quasars must exceed 10 megaparsecs, well beyond the local group of galaxies. The best interpretation at present is to ascribe most of the red-shift to Doppler effect, but allow a considerable contribution from gravity. The quasars are then very massive, containing  $10^9$ – $10^{11}$  solar masses, concentrated in large stars or protostars, and with dimensions of only a few parsecs. They contain the mass of a whole galaxy compressed to a size equal to the distance between the Sun and the nearest star.

The radio emission from some quasars changes appreciably in a few weeks, and the light emission may change within a day. Clearly some very large events are occurring in a very small space, as they do in a supernova explosion. There could, for example, be  $10^7$  or more large stars exploding or colliding, several times per year, keeping the quasar shining for  $10^5$  or  $10^6$  years. This is long enough to allow some material ejected from 3C 273 to have reached an elongation of  $19''$  arc.

Fig. 4. The varying visibility of the radio interferometer fringes obtained from quasar 3C 298 as observed through 12 h of Earth rotation. The deep minimum indicates that the source is double. These fringes were obtained at a frequency of 408 Mc/s on a baseline of 180,000 wavelengths.

On this view the lifetime to be used in the calculation of energy could be shorter than  $10^5$  years but not so much shorter that the problem is significantly changed. We are in any event faced with the same problems for radio galaxies, the distances and lifetimes of which are much better known. Catastrophic releases of energy must occur; the extra problem of the quasar is the extreme concentration of the energy.

The arguments so far, which are due to many authors, notably Hoyle and Fowler<sup>3</sup>, and McCrea<sup>4</sup>, are converging on the idea of a distant, massive, condensed nebula. Some serious difficulties remain.

(1) The radio galaxy 3C 47 has an optical quasar at its centre. If quasars are related to radio galaxies, why are radio galaxies commonly found to be bright elliptical galaxies in clusters, while quasars are not associated with clusters?

(2) Why are quasars often double radio sources? There is even one pair of unidentified quasar-like sources, 3C 343 and 3C 343.1, which are 28 min of arc apart, which is 17,000 times their angular size. These two are identical in many of their detailed radio characteristics.

(3) How can any mechanism concentrate so much of the total available energy into electrons and magnetic field?

These problems are unanswered. The surprising thing is that such strange and inaccessible objects as quasars can have been the subject of such rapid advances recently, both in observations and in theory. The excitement is surely not yet over.

Further reading will shortly be available in books by G. R. and E. M. Burbidge (*Quasi-Stellar Objects*, Freeman, London) and by F. D. Kahn and H. P. Palmer (*Quasars*, Manchester University Press). The Physical Society and the Institute of Physics, together with the Royal Astronomical Society, are arranging for a conference on "The Physics of Quasars" to be held in Manchester during September 5-7, 1967.

(continued from page 966)

exposures taken at such instants of best seeing. The original purpose was to get improved lunar and planetary pictures, where the object to be photographed is available for periods of the order of an hour. Laboratory tests have been made (*Nature*, **203**, 274; 1964), and experimental lunar photography is under way. Some thought has been given to the problems of photographing fast-moving artificial satellites.

The other scheme is an electronic image stabilization system developed by Itek Corporation (Lexington, Massachusetts). Optical feedback and magnetic deflexion coils are used to keep the image of a small object, or the centroid of a larger image, fixed on the retina of an electronic image tube in spite of actual motion of the object, the propagating medium or the image tube mount. A prototype system has been tested extensively, and shows good frequency response up to 2,000 c/s. It appears reasonable that the system would work satisfactorily on a large telescope.

The general conclusion of the study was that image processing has advanced to the stage at which it is ready to make the step from experimental procedure to useful operational tool; in particular, it was recommended that Harris's digital processing techniques should be applied to real telescopic images as soon as possible, and that work should be pushed in the other areas to increase understanding and to develop more effective techniques and equipment.

## BOOK REVIEWS

### NEWTON'S PROGRESS

#### The Background to Newton's *Principia*

A Study of Newton's Dynamical Researches in the Years 1664-84. By John Herivel. Pp. xv+337+5 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1965.) 70s. net.

THIS work is a detailed study of Newton's dynamical researches during what was the most fruitful period of his life. In 1664 Newton came under the tutelage of Isaac Barrow; the following year he was compelled by the Great Plague to seek shelter in his native Woolsthorpe, and it was during his sojourn there that were laid the foundations of his future greatness. "All this," he wrote later, "was in the two plague years 1665 and 1666, for in those days I was in the prime of my age for inventions, and minded mathematics and philosophy more than at any time since."

It is to this period that can be traced the beginnings of those researches which were to prove of immeasurable value to science. Was the force which drew the apple to the ground the same as that which retained the Moon in her orbit? "In the same year" (1666), he wrote, "I began to think of gravity extending to the Orb of the Moon . . . having thereby compared the force requisite to keep the Moon in her Orb with the force of gravity at the surface of the Earth, and found them to agree pretty nearly." Thus began those investigations which led to the enunciation of the principle of Universal Gravitation.

On the cover of this book it is stated that Mr. Herivel's work is "devoted exclusively to Newton's dynamical thought leading up to the composition of the *Principia*". On this account, its appearance is all the more welcome. Only a fraction of Newton's vast output was made public during his lifetime; much of it has been hidden away for close on three centuries. A detailed study of the steps which led to the production of this monumental work is therefore long overdue, and we are grateful to Mr. Herivel for the painstaking way in which he has analysed Newton's original documents and presented them in a way which compels the reader's attention.

The book is divided into two parts. Part I is devoted to an extended commentary on the manuscripts which form the substance of Part II. In the early pages of Part I the main line of development of Newton's dynamical thought is traced. Apart from the contributions of Galileo, mechanics had made little headway during the early decades of the seventeenth century. Newton inherited much from Galileo, and Mr. Herivel rightly assesses the value of this inheritance. But he is far too kind to Descartes, whose notions on fundamental ideas were vague in the extreme. Motion, according to Descartes, was nothing more than the transport of a body from the vicinity of those in contact with it to the vicinity of others (*Prin. Phil.*, II, 25). It is thus contrary, not to a motion in the opposite direction, but to rest. To say that a body in motion possesses a certain "force" to resist any change in its state is not at all helpful if we are not told how this force is measured. Mr. Herivel tells us (on page 53) that "it seems probable that Newton took the idea of using momentum (and its conservation) in collision processes directly from Descartes". But did not Descartes base his conclusions on divine immutability? God always preserves in the Universe the same amount of motion as He created in it. Mr. Herivel is clearly aware of the weakness of Descartes's exposition when he tells us (on page 52) that "the laws of collision given by Descartes in Part II of the *Principia* were notoriously full of error".

He might have added that the simplest of experiments would suffice to disprove them, as Clerselier clearly pointed out. It is therefore no injustice to Descartes to declare, as did Whewell in the *History of the Inductive Sciences*, that "if we were to compare Descartes with Galileo, we might say that of the mechanical truths which were easily obtainable at the beginning of the seventeenth century, Galileo took hold of as many, and Descartes as few as was well possible for a man of genius".

Chapter 6, on order of composition and dating of manuscripts, is particularly valuable inasmuch as we learn from it the extent to which Newton was treading on virgin soil, and, here again, Mr. Herivel has placed us heavily in his debt. Newton, like so many of his contemporaries, was often careless as to dates, and in giving a precise chronology of the steps leading to the publication of the *Principia*, Mr. Herivel has rendered a very useful service.

One of the most valuable features of this work is the comprehensive index which has been supplied, and this the reader will find most helpful. If, and when, a second edition of this work is planned, Mr. Herivel might consider the provision, in an appendix, of brief biographical notes on some of the lesser known persons mentioned in its pages. Not every reader is familiar with the contributions of such men as Borelli, Bradwardine, Gassendi or Paget, to name but a few.

*The Background to Newton's Principia* is a work which should have a place on the bookshelves of all who are interested in the history of science during the illustrious seventeenth century.

J. F. SCOTT

## LECTURES ON MOLECULAR SPECTROSCOPY

### Molecular Spectroscopy—VIII

(Invited Lectures presented at the VIIIth European Congress on Molecular Spectroscopy, held in Copenhagen, Denmark, August 14–20, 1965.) (*Pure and Applied Chemistry*, Vol. 11, Nos. 3–4, 1965.) Pp. vi + 261–582. (London: Butterworth and Co. (Publishers), Ltd., 1966.) 75s.

THE organizers of the eighth European Congress on Molecular Spectroscopy at Copenhagen have been wise in restricting the publication to the invited papers presented at this meeting. They represent useful summaries or reviews of various topics, and any objections to the publication of conference proceedings in general do not apply to the present volume. The meeting in Copenhagen was a very large meeting with about 800 participants and many parallel sessions were necessary. Consequently, it was not possible for an individual participant to attend all the invited lectures, and it is very useful to have all (or almost all) the invited lectures collected together in one volume. The meeting in Copenhagen may have been the last meeting to cover the whole of molecular spectroscopy. Correspondingly, the present volume deals with a large variety of topics, several of them extremely well presented.

Many of those who attended the meeting will remember the beautiful opening lecture of Professor Daudel on the role of wave mechanics in the interpretation of molecular spectra. It is a fine summary which clearly brings out the constant dialogue between theory and experiment in the development of both the detailed theory of small molecules and the semi-empirical theory of large molecules. There are several other invited theoretical lectures, in which I. M. Mills considers the effect of Coriolis interactions on rotation-vibration spectra and is able to present examples which show the possibility of obtaining information about the potential functions from the effects of Coriolis interactions; H. Preuss deals with the potential functions of polyatomic systems; G. J. Hoijtink deals

with triplet-triplet spectra of alternant hydrocarbon molecules; J. T. Hougen gives a thorough discussion of the vibrations in molecules with nearly free internal rotations; and I. Fischer-Hjalmars presents a theoretical study of systems with heteroatoms.

In addition to these theoretical papers, there are a number of excellent papers on experimental subjects. Many will remember the very fine lecture by Mössbauer, who showed how the effect bearing his name can be applied to problems of electronic shielding in the rare earths. This paper deals, in other words, with the spectroscopy of very small wavelengths, that is, gamma radiation. There is very little discussion of the vacuum ultra-violet region or of spectra of diatomic molecules, at least in the invited papers, but the visible and near ultra-violet spectra of polyatomic molecules are well represented. Th. Förster deals with the polarization of the photoluminescence in solutions. M. Kasha deals with the exciton model and its use in the interpretation of the spectra of aromatic molecules, and H. Kuhn reports on very interesting experiments in which simple organized systems of molecules are built up and their absorption and fluorescence are investigated as a preparation for an understanding of biological structures.

A very stimulating paper is presented by B. P. Stoicheff on molecular spectroscopy with optical masers. Apart from giving a very useful summary of the present status of this field, he reports his recent discovery of the inverse Raman effect.

In line with the historical development of the European molecular spectroscopy meetings, a good deal of emphasis remains with vibrational spectroscopy. (The ninth meeting in Madrid next September is to be devoted entirely to this subject.) D. Hadzi reports on the infra-red spectra of strongly hydrogen-bonded systems, while L. A. Woodward discusses the Raman spectra of aqueous solutions, and D. O. Hummel describes the infra-red spectra of macromolecules. One of the most interesting developments reported at this meeting is the first success in obtaining infra-red spectra of free radicals produced by flash photolysis. This work is described by G. C. Pimentel in his invited lecture and at the meeting it was also discussed by R. M. Hexter in one of the contributed papers (not included in this volume).

Microwave spectroscopy is represented by the lectures of two of the pioneers in this field. W. Gordy reports on the extension of microwave spectroscopy into the sub-millimetre region, while J. Sheridan discusses some recent results and future trends in microwave spectroscopy.

Only one of the invited papers, that of R. A. Hoffman, deals with nuclear magnetic resonance spectra; in particular, with the analysis of high resolution spectra of this type. Finally, there are two important papers on spectroscopic technique. H. A. Gebbie describes the important developments in the field of interference spectroscopy to which he himself has made such fine contributions, and P. L. Richards describes the latest developments in infra-red detectors.

All in all, this volume represents a very useful summary by competent authors of some of the most important topics in spectroscopy. The book is well printed, and, in particular, the half-tone reproductions are well done. The lectures are published in the original language of the particular authors although the actual presentation of most of the lectures was in English. G. HERZBERG

## BROMINE HANDBOOK

### Bromine and Its Compounds

Edited by Z. E. Jolles. Pp. xxvii + 940. (London: Ernest Benn, Ltd., 1966.) 210s. net.

THIS book deals with almost every conceivable aspect of the chemistry of bromine and its compounds. There

are chapters by the editor, Dr. Jolles, and by twenty-three other authors from a large number of industries and universities. The book is divided into seven sections: the manufacture and physical and chemical properties of elemental bromine; inorganic bromine compounds; organic bromine compounds—this deals mainly with methods of bromination and related reactions, for example, addition, substitution and elimination; radioactive bromine and bromine in radiation chemistry; biological aspects of bromine and its compounds; industrial applications; and analytical chemistry of bromine and its compounds (including applications of most types of spectroscopy).

Such a multitude of topics are covered that an exhaustive appraisal would require a reviewer of exceptionally catholic tastes, but it is clear that the editor and his co-authors have produced an important reference work, and that they have largely succeeded in one of their objectives which was to summarize existing knowledge of bromine and its compounds. They also hope to stimulate the use of bromine and its compounds as an alternative to chlorine and its compounds, particularly in industrial processes, and the book will be invaluable to anyone considering this.

The cost and contents are such that the book will be bought by few individuals although all libraries should consider it an essential acquisition. This raises two points. At present the book stands alone: its value would be enhanced if it were accompanied by companion volumes on the other halogens. The direct orientation towards bromine chemistry also conflicts to some extent with the comparative approach which is so useful in dealing with the properties of the halogens.

Finally, a good point—the book is relatively free from errors—and a criticism—the references given to the thermodynamic properties of bromine are obsolete.

E. WHITTLE

## TASMANIAN JOURNAL

### Friendly Mission

The Tasmanian Journals and Papers of George Augustus Robinson, 1829–1834. Edited by N. J. B. Plomley. Pp. xiii + 1074 + 17 plates. (Hobart: Tasmanian Historical Research Association, 1966.) A.126s.

ALTHOUGH the aboriginal tribes of Tasmania were in contact with Europeans for some decades before they finally became extinct (approximately from 1770 to 1870), there is nevertheless very little worthwhile information about them. Before the publication of the book under review, much of the information was provided by the records of French explorers during the late eighteenth and early nineteenth centuries. The Robinson papers, missing for many years, therefore provide a large additional source of information on these people.

George Augustus Robinson began his work among the aboriginals in very troubled times, and was successively conciliator of the Tasmanian tribes, commandant at the Flinders Island aboriginal settlement, and chief protector of the aborigines at Port Phillip. During this time he kept various records of his work with these people, most important being his field journals. The book is mainly concerned with the period 1829–1834, giving a day by day account of his experiences with the tribes—and in the case of some of them, his information is all that we have.

The mass of writing left by Robinson was by no means orderly, and the editor has clearly been to great pains to sort and cross-check names, localities and other information. Additional hazards for him were poor writing and early nineteenth century punctuation (or lack of it). Plomley is to be congratulated on his careful and scholarly editing, and in lacing the journals together so well with the many additional notes.

The book is of value not only as a source of information about the physical and social anthropology of the indigenous Tasmanian, but also as a remarkable chapter in colonial history. To quote Plomley's apt comment about Robinson: "Usually humanity is a principle rather than a course of action. To find someone living up to his belief that all men are born equal but suffer from inequality of opportunity was and is extraordinary". Alas, all the good intentions of Robinson and certain other administrators only hastened final extinction.

Increased mortality resulting from early conflict with European settlers, and a decrease in births following the enslavement of numerous aboriginal women by the sealers, was followed by increasing mortality through European-introduced diseases.

In addition to the journals, there are valuable extra sections and appendixes compiled by the editor. These review the prehistoric background, biological affinities and variation in the Tasmanians; also the distribution and names of the numerous small tribes. The appendixes also provide a geographical check-list of aboriginal and alternative European place names, a review of the natural history of the country, and a useful summary.

D. R. BROTHWELL

## MENTAL SET

### The Psychology of Set

By D. N. Uznadze. (The International Behavioral Science Series.) Pp. xvii + 251. (New York: Consultants Bureau, 1966.) \$15.

THIS book appears in the International Behavioral Science Series, for which Dr. Joseph Wortis is the general editor. Other translations from the Russian in the same series are A. R. Luria's *Higher Cortical Functions in Man* (1966) and B. V. Andreev's *Sleep Therapy in the Neuroses* (1960).

Dmitrii Nikolaevich Uznadze (1886–1950) was for many years director of the Institute of Psychology of the Georgian Academy of Sciences in Tbilisi, where visitors today are hospitably received by Professor Prangishvili, one of his close collaborators and a former colleague. For many western readers, the first acquaintance with Uznadze's work probably came in the 1920s through the pages of the German journal, *Psychologische Forschung*, which published articles deriving from the Gestalt school. Since then odd papers have appeared in proceedings of conferences and in a few western journals, but the present work is the first systematic presentation of the approach of Uznadze and the Georgian school to be available generally in the West. It comprises two monographs, *Experimental Basis of the Psychology of Set*, originally written in Russian, but first published in the Georgian language in 1949, and *Basic Principles of the Theory of Set*, also written in Russian, which has not hitherto been published.

The influence of a "mental set" has long been known. A common example is the way in which one "sees" or "hears" the approach of the expected visitor only to find that other stimuli have been biased or distorted by the pre-existing "set" of thought. The book deals with methods of establishing sets experimentally in visual, auditory and kinesthetic modalities. A set established for one hand can "irradiate" to the other, spontaneously, and so too, particularly with young children, sets may transfer from one sensory modality to another. Individuals differ appreciably in the readiness with which sets can be formed, retained and generalized to other situations. Qualitative stages in the extinction of a set, such as the "plastic", "coarse" or "inert" forms, are distinguished. Sets may be established in animals such as rats, chickens and chimpanzees, a field of work where a keen debate could develop between those who would prefer to use the language of the "set" theorists and others who would

favour the terminology of learning theory and reinforcement. Talented actors can acquire a set described to them and maintain it much more precisely than others and some interesting possibilities of distinguishing the course of sets peculiar to schizophrenics and epileptics are outlined.

The methods used and the findings established in the many experiments described are usually not presented in great detail, but frequently in the form of conclusions. This has the merit of ensuring a wider coverage of topics within a shorter space; but would tend to limit precise repetition of the experiments. Nevertheless, psychologists who are interested in the experimental study of the thought processes, a very basic field of study, are presented with a valuable sketch of a considerable body of work already done and many possibilities for future experiments.

F. V. SMITH

## BASIS OF INTELLIGENCE

**Genetic and Environmental Factors in Human Ability**  
Edited by J. E. Meade and A. S. Parkes. (A Symposium held by the Eugenics Society in September–October 1965.) Pp. xi+242. (Edinburgh and London: Oliver and Boyd, Ltd., 1966.) 57s. 6d.

THE editors and the Eugenics Society are to be congratulated on an outstanding symposium in which a distinguished group of authors present a series of lucid and concise papers on the nature–nurture problem in human intellectual performance. The book deserves to be read by every student of psychology, genetics and the social sciences and by all who are concerned with education, social medicine and social welfare either as teachers, practitioners, administrators or policy makers.

After a brief introduction by Sir Robert Platt, the book is divided into four sections. In the first section, on intelligence tests, P. E. Vernon outlines the problem, B. B. Bernstein and D. Young report new work on the effects of relationships between mother and child, Hilde Himmelweit summarizes her work on social influences in school and Douglas Pidgeon discusses the effects of intelligence tests on British education.

In the second section Jean Floud discusses the problem of selection for university places; Stephen Wiseman summarizes evidence on innate and environmental factors in educational attainment; James Drever tells a cautionary tale to ask how far abilities are influenced by parental ambitions; and Liam Hudson describes some of his research relating test results to achievement at university and after. The section is briefly summed up by Lord Robbins.

The third section deals with causes of sub-normality and includes a lively contribution by James Walker on the effects of perinatal accidents and their relation to social factors. It also contains a discussion by Albert Kuschlick of the interaction between physical, social and mental factors, an account by C. E. Dent of genetically caused biochemical abnormalities affecting mental function, and a summary by Valerie Cowie of associations found between chromosomal abnormalities and mental defect. The section ends with a brief statement by Brian Kerman.

The papers in the last section are on the relationships between intelligence and fertility. B. Benjamin summarizes census data from several countries; C. O. Carter indicates that the fertility of the more intellectually able sections of the population is tending to rise; R. M. C. Huntley outlines elegant research comparing genetic influences on intelligence, on certain physical measures and on social adjustment; and D. S. Falconer considers the consequences of selection pressure on genetic factors in intelligence. J. A. Fraser Roberts makes a short concluding statement.

The contributions from psychology, genetics, education and medicine complement each other in a way which

realizes the aim of a true symposium: where one discipline is equivocal another is definite, where one is emphatic another may qualify. The only really disappointing papers are those by Douglas Pidgeon and Jean Floud, whose essentially political statements on education appear thin beside the scientific contributions. The time seems to be coming when education should be taken out of party politics, for a more rational approach is now evident.

A. T. WELFORD

## NERVOUS MECHANISMS

### Nerve as a Tissue

Edited by Kaare Rodahl and Bela Issekutz, jun. (Proceedings of a Conference held at the Lankenau Hospital, Philadelphia.) Pp. x+470. (New York and London: Hoeber Medical Division, Harper and Row, Inc., 1966.) \$18.50; 148s.

THE Lankenau Hospital research conference in November 1964 provided a unique opportunity for the discussion of a wide range of topics related to nerve and synaptic mechanisms. An impressive list of contributors assured the success of the conference and has resulted in a volume of undoubted value. The book is divided into four major sections: morphology, biochemistry, physiology and pharmacology, and the pathophysiology of nervous tissue. Within these sections the chapters present a coherent, sometimes controversial, and always stimulating, account of nervous mechanisms. Seventeen topics are covered in the book but, unfortunately, comment must now be limited to only a brief mention of a few of these.

The first chapter describes and illustrates the organization of the cell membrane, and E. de Robertis describes the biochemistry of subcellular fractions and provides evidence for the compartmentalization of 5-hydroxytryptamine and catecholamines.

The biochemistry section begins with a chapter by D. Nachmansohn in which he delivers his customary attack on the generally accepted views of neuromuscular transmission and nerve conduction. The arguments he uses lean, more heavily than usual, on the existence of rather inscrutable permeability barriers and on the cursory dismissal of well established experimental results. In a subsequent chapter these arguments are concisely and effectively dealt with by G. B. Koelle. It is hard that Nachmansohn should tell us that there is "no alternative" to his views, especially when misleading interpretations of experimental facts are made which have to be pointed out in the illuminating discussion which follows.

A balanced analysis by W. Nastuk and A. Gissen of the effect of depolarizing drugs at the muscle endplate leads to a reasoned explanation of the puzzling nature of "dual block" in terms of chemodesensitization.

Evidence for the identity of centrally transmitting chemicals is reviewed by D. Curtis, and he reasonably concludes that, although there is suggestive evidence indicating that several compounds may transmit, only acetylcholine at Renshaw cells can be considered, with any certainty, to be a transmitter. Progress in this topic has been rapid since the conference and further evidence has now accumulated to implicate acetylcholine and  $\gamma$ -aminobutyric acid as transmitters in the cerebral cortex.

The section on pathophysiology contains an intriguing chapter by A. Ward on the hyperexcitable neurones which are found in focal epilepsy. He describes the characteristics of these cells and the way in which they lose their dendritic spines. The abnormal quantal release of acetylcholine in myasthenia gravis is considered by D. Elmquist and, supported by experimental evidence, he suggests some possible defects in the transmitter mechanism that may occur in this disease. The volume ends, appropriately, with an appendix by Sir John Eccles on the strategy of neurophysiological research.

This book is exceptionally well produced and should appeal to all who have an interest in nervous mechanisms. The features one hopes for in a conference report of this kind are all present and include abstracts of chapters, author and subject indexes, full bibliographies and coverage of the discussions which followed each section of the conference.

J. F. MITCHELL

## MONOGRAPH ON NORADRENALINE

### The Uptake and Storage of Noradrenaline in Sympathetic Nerves

By Leslie L. Iversen. Pp. xiv + 253 + 8 plates. (London: Cambridge University Press, 1967.) 57s. 6d. net; \$11.

DURING the past decade there has been a remarkable increase in our knowledge concerning the neurotransmitter, noradrenaline. This development has been stimulated by the availability of specific and sensitive methods for the isolation and measurement of noradrenaline in tissues. These include the introduction of radioactive catecholamines of high specific activity; new histofluorescent techniques that make sympathetic nerves visible; and the sophisticated use of drugs that affect the adrenergic system. Thus, contributions have come from a variety of disciplines, including biochemistry, pharmacology, physiology and anatomy. In this monograph Dr. Iversen gives a lucid, informative account of our current knowledge of the formation, uptake, storage, release and metabolism of noradrenaline in peripheral sympathetic nerves, as well as in the central nervous system.

The first portion of the book describes the methodology for the chemical estimation of catecholamines, the pathways and enzymes involved in their biosynthesis and metabolism, the release of noradrenaline from nerves and its subsequent fate. A considerable portion of the remainder of the book deals with a newly discovered process which causes the rapid inactivation of the adrenergic neurotransmitter by uptake across the neuronal membranes and storage in vesicles within the sympathetic neurone. The uptake and release of noradrenaline in nerves and the action of adrenergic drugs are described in considerable detail. The author is very knowledgeable in this subject and he has made many of the significant contributions. Recent work on the exciting topic of the localization, storage and release of noradrenaline and other biogenic amines in the central nervous system and the effect of psychoactive drugs is described in the last chapter.

In this book considerable controversy is generated by conflicting theories, as is the case in most rapidly emerging fields of research. Dr. Iversen handles controversial questions critically but fairly, and places them in proper perspective. This monograph is concerned with an important problem in the biomedical sciences, and it should appeal to the general reader as well as the specialist.

JULIUS AXELROD

## PARASITIC PROTOZOA

### Malaria Parasites and Other Haemosporidia

By P. C. C. Garnham. Pp. xviii + 1114. (Oxford: Blackwell Scientific Publications, 1966.) 175s. net.

STUDENTS of the malaria parasites and other haemosporidia have depended on Wenyon's *Protozoology* as an indispensable guide for four decades. In the meantime, knowledge of these parasites has increased tremendously and a great need has developed for a modern book of comparable depth and quality. This book admirably fulfils the need with respect to the haemosporidia. It deals primarily with protozoology in both vertebrate and invertebrate hosts; clinical aspects, epidemiology, im-

munity and pathology of malaria are discussed when they have a direct bearing on the parasites.

Part I is a general review of the discovery of malaria parasites, their life cycle and morphology, classification and evaluation, and biochemistry. Part II, on the Plasmodiidae, starts with taxonomy, in which the mammalian parasites are divided into the sub-genera *Plasmodium*, *Laverania* and *Vinckeia*. It continues with detailed descriptions and illustrations of each mammalian species. The avian sub-genera *Haemamoeba*, *Giovannolaia*, *Novyella* and *Huffia* are reviewed next, and the species of avian parasites are described. This part of the book is completed by a review of the reptilian sub-genera *Sauramoeba*, *Carinamoeba* and *Ophidiella* along with descriptions of the species of parasites known in lizards and snakes.

Part III, on the Haemoproteidae, includes *Hepaticystis*, *Haemoproteus*, etc., and Part IV discusses and describes species in the family Leucocytozoidae. Malaria parasites of doubtful status are reviewed in Part V. The final part of the book is a quite detailed description consisting of sixty-five pages of technical procedures for use in the identification of malaria parasites and studies of their life cycles.

The morphology and staining reactions of the parasites are presented in numerous coloured plates of excellent quality. Extensive reference to the literature is made throughout, which results in a useful but understandably incomplete bibliography on each subject. Taxonomy is traditionally controversial and some authorities may not concur fully with the author's decisions.

The volume is recommended as a reference book for malariologists, protozoologists and others concerned with the laboratory diagnosis of malaria, as well as a text-book for students of parasitology.

PAUL E. THOMPSON

## PLANT MALADIES

### Annual Review of Phytopathology

Vol. 4. Edited by James G. Horsfall in Association with Kenneth F. Baker. Pp. vii + 423. (Palo Alto, California: Annual Reviews, Inc., 1966.) \$8.50.

THIS volume, which follows the format of its predecessors, contains sixteen articles which between them cover a wide field of phytopathology. Dixon Lloyd Bailey, in an introductory chapter assessing the present position of plant pathology, detects an increasing trend among pathologists to escape from the rigid boundaries of established disciplines, and he welcomes the development of an awareness and willingness to apply relevant discoveries in pure science. Few would disagree with him. E. C. Large reviews disease measurement, particularly in Britain. Grogan and Campbell contribute an article on fungi as vectors and hosts of viruses. In addition to the now established relationship of lettuce big vein and tobacco stunt viruses with *Oidium brassicae*, they suggest that tobacco necrosis may also prove to have a connexion with this fungus. The evidence for the possible association of cereal viruses with *Polymyxa graminis* is reviewed. The present volume also contains articles on chemical soil treatments by S. Wilhelm; virus transmission in woody plants by R. W. Fulton; air pollution in plant pathology by J. T. Middleton; pectic enzymes in tissue degradation by D. F. Bateman and R. L. Millan, and sections on host-pathogen interactions. These include epidemiology, by J. E. Crosse and K. F. Baker, and S. H. Smith, the action of toxicants—a paper on synergism among fungicides by Anna Scadavi—and chemical control—amino-acids and plant diseases by O. M. van Andel. The action of oil in disease control is discussed by L. Calpouzos, who presents a critical evaluation of experimental results, both published and unpublished, on the value of oil sprays in the control of plant

diseases, in particular banana leaf spot, *Mycosphaerella musicola* Leach. Effective oils apparently achieve their results in a number of ways and their effects appear to be on the disease itself rather than directly on the pathogen. For this reason the author prefers "antidisease agents" to "fungicides" for use in describing them.

There are author and subject indexes for the present volume and cumulative indexes of authors and titles for Volumes 1 to 4. The present volume has maintained the standard set by its predecessors and the series remains essential reading for plant pathologists. J. H. WESTERN

## CHEMISTRY AND PHYSICS OF LIPIDS

### Chemistry and Physics of Lipids

Edited by G. H. de Haas and five others. (Volume 1, No. 1; 1966/67.) Pp. 89. (Amsterdam: North-Holland Publishing Company, 1966.) n.p.

THE new journal, *Chemistry and Physics of Lipids*, first appeared in November 1966. The declared editorial policy of this new journal is to publish papers in the field of molecular biology, with particular emphasis on the chemical and physical aspects of lipids. At present there is already a journal exclusively devoted to lipid research and it is by no means bursting at the seams. Moreover, *Biochimica Biophysica Acta* offers a whole section for papers on the biochemistry and biophysics of lipids. One wonders what prompted the editorial board and publishers of *Chemistry and Physics of Lipids* to launch a new journal in this field. They may have felt that a journal should be exclusively devoted to the biophysics of lipids, but surely this is carrying super-specialization too far.

It is not easy to applaud the purposes of a journal the editorial board of which sees the chemistry and physics of lipids as a cloistered enclave insulated from the hurly-burly of general biological research. If this process of super-specialization proceeds much further, the time will come when a scientist will only be able to communicate with himself, because nobody else will understand his jargon.

It would be churlish not to wish success to this new journal. Nevertheless, if it should fail to thrive for lack of real support, it is to be hoped that the publishers will consider whether or not to continue its publication. There are already too many specialized journals that are barely viable: to add to their number serves no useful purpose.

C. W. M. ADAMS

## THE DRUG SCENE

### Extra Pharmacopoeia (Martindale)

Incorporating Squire's Companion. Edited by R. G. Todd. Twenty-fifth edition. Pp. xxviii + 1804. (London: The Pharmaceutical Press, 1967.) 150s.

THE twenty-fifth edition of Martindale is obviously destined to become a *vade mecum* for the increasingly harassed druggist and the equally tormented prescriber. The drug scene, as the popular press keeps reminding us, is getting out of hand. No one is more aware of this than the editor of a comprehensive pharmacopoeia—the editor of this one, Mr. R. G. Todd, writes in his introduction of the "formidability" of the task that faced him after the publication of the twenty-fourth edition in 1958. Since that time more than 1,200 drugs have been admitted to the book, and the number of new proprietary products developed over the same period is 2,400. The task of compiling a directory to all these compounds would daunt the bravest, but Mr. Todd has put together a comprehensive and even readable guide.

The first part of the book consists of monographs on the chief drugs of clinical and toxicological importance, the

drugs being grouped together according to their properties where possible. The articles on individual drugs are accompanied by quotations from articles in the medical and pharmaceutical press. The second part is a list of supplementary drugs of lesser importance. There is also a list of proprietary substances usually supplied "over the counter" on request, a list of manufacturers and a classification of drugs by the disease for which they are normally used. The index is unusually comprehensive and the book should be on the bookshelf of everyone who needs a guide to modern drugs.

JOHN SPENCER

## OBITUARIES

### Professor H. Munro Fox

HAROLD MUNRO FOX, who died on January 29 at the age of 77, was a zoologist of great distinction. His scientific output began with a series of ten papers, mostly on fertilization, hybridization and inheritance in sea urchins, published between 1911 and 1915. After an interlude as an officer in the Army Service Corps, London Mounted Brigade, he resumed his researches in the early twenties with a group of papers on various subjects: lunar periodicity; migration of invertebrates through the Suez Canal; animal orientation; reactions of flagellates to low oxygen tension and their use in detecting the respiratory surfaces of small invertebrates, and the chemical nature of chlorocruorin. Soon he settled down to a "main line" of work on invertebrate respiration. He was professor of zoology in the University of Birmingham during 1927–1941 and at Bedford College during 1941–1954, and finally professor emeritus and honorary research associate at Queen Mary College. For the whole of this time a steady stream of important papers flowed from Fox and his pupils, on such subjects as the nature and functions of the respiratory pigments haemoglobin and chlorocruorin; the relation of metabolic rate to environmental temperature and oxygen tension; the regulation of respiratory movements; and invertebrate blood circulations. At first, these papers were mostly concerned with worms, but later he produced a series of important works on the respiration physiology and haemoglobin of crustacea, especially *Daphnia*. This led him on to investigate the taxonomy and general biology of freshwater crustacea, with which his latest papers are concerned.

Fox was elected to the Royal Society in 1937, and was Fullerian professor of physiology at the Royal Institution from 1953 to 1956. He was awarded a gold medal by the Linnean Society of London in 1959, and the Darwin Medal of the Royal Society in 1966.

The whole of Fox's work is characterized by great clarity and precision, shown both in his experimental methods and in the style of his writing. His interest in the life of the animals on which he worked was unflagging. He was an indefatigable field naturalist, and honorary president of the London Natural History Society. His friends will remember the spotlessly clear marine aquaria in his London flat, where the most delicate animals thrived and bore witness to his devotion. He was also a great European, spending his working holidays at laboratories abroad, especially in France and Italy. He served as president of the International Union of Biological Sciences from 1950 to 1953.

His enthusiasm and precision made Fox a first-class teacher, and also—together with his international outlook—fitted him for his forty years in the editorial chair of *Biological Reviews*, a position which he occupied from the origin of that journal in 1926 until his death. He was indeed an outstanding scientific editor, and in building up *Biological Reviews* he made perhaps the greatest of all his contributions to the advancement of biology.

# Pressure History of some Iron Meteorites

by  
R. R. JAEGER  
M. E. LIPSCHUTZ

Department of Chemistry,  
Purdue University,  
Lafayette, Indiana

Comparisons with artificially shocked standards show that many iron meteorites have been shocked at pressures of at least 130 kilobars. These shocks probably originated from preterrestrial collisions, rather than from impact with Earth.

DURING the past few years, metallographic investigations have shown that shock pressures in excess of 130 kbars resulted in a number of microstructural changes in Grant and Canyon Diablo iron meteorites<sup>1-3</sup>. More recently, we have observed<sup>4</sup> that single crystals of meteoritic kamacite ( $\alpha$  Fe), cohenite ( $\text{Fe}_3\text{C}$ ) and schreibersite ( $\text{Fe}_3\text{P}$ ) are transformed, during artificial shock, into aggregates showing preferred orientation on X-ray diffraction investigation. Preferred orientation was also observed in grains of the same minerals from naturally shocked Canyon Diablo samples<sup>4</sup>.

Two previous reports<sup>5,6</sup> have mentioned that kamacite from eight additional iron meteorites showed unusual X-ray diffraction features ("asterism" or diffuse Laue spots). We thought that these abnormalities might indicate that the kamacite had been severely shocked, so we obtained a number of specimens of four of these (Table 1) for investigation by metallography and X-ray diffraction. In addition we investigated a number of samples of the Magura meteorite as it has been reported to contain diamonds<sup>7</sup> which may have been formed by shock<sup>8</sup>. Finally, we wished to make use of these observations in estimating the percentage of iron meteorites which have been severely shocked at some time during their history.

The metallographic and X-ray diffraction techniques used and the shock standards have been described elsewhere<sup>2,3</sup>. Although the microscopic shock-induced changes have been previously described in detail<sup>3</sup>, we shall review them briefly. Fig. 1 illustrates the appearance of Odessa samples shocked to 200 (a), 400 (b) and 600 kbars (c). The principal feature in Fig. 1a is the dense, fine-grained appearance of the  $\epsilon$ -iron structure. The localized nature of this feature in meteorites shocked to 200 kbars probably arises from differences in the relative orientation of the kamacite grains<sup>3,8</sup>. The 600 kbar transformation structure, which consists of a clearly resolvable background and Neumann bands with well developed transverse hatching (Fig. 1c), is readily distinguishable from that at 200 kbars<sup>3</sup>. X-ray diffraction patterns of kamacite, cohenite and schreibersite from such samples show pronounced preferred orientation, even if the regions from which the specimens were taken show no microscopically observable changes<sup>4</sup>.

The kamacite exposed in the polished surfaces of the meteorites Narrabura and Spearman uniformly shows a clearly resolvable  $\epsilon$ -iron transformation structure and "feathered" Neumann bands (Fig. 2a). The structure in

Narrabura has also been observed by Buchwald and Axon<sup>10</sup>. In Narrabura the kamacite grains in the very coarse plessite ( $\alpha$ - $\gamma$  iron mixture) even show this structure. The kamacite of both exhibits pronounced preferred orientation on X-ray examination. The phosphide grains of both meteorites show extensive fracturing and, in Spearman, corrosion (probably caused by terrestrial weathering). Based on comparison with shock standards, these meteorites apparently have been shocked to 400-600 kbars.

As in Narrabura and Spearman the  $\epsilon$ -iron transformation structure in Coopertown is present throughout the kamacite. It (Fig. 2b) closely resembles the 600 kbars standard, however, indicating that this meteorite was shocked to a somewhat higher pressure than were the first two. The plessite grains are somewhat less dense than in Spearman and there is localized kamacite recrystallization between the "teeth" of the comb-like plessite grains. The schreibersite grains are corroded although the rhabdites show sharp borders. The kamacite grains show preferred orientation.

All the specimens of Magura which we investigated showed patches of the  $\epsilon$ -iron transformation structure (Fig. 2c) previously observed<sup>10</sup> as well as regions of apparently unaltered kamacite. In the body of the transformation regions, the structure resembles the 200 kbars variety, while at the grain boundaries the structure was similar to that seen in Odessa samples shocked to 400 kbars. Some schreibersite and cohenite grains showed fracturing but no corrosion was apparent. Kamacite and cohenite grains showed preferred orientation on X-ray examination. We conclude that these specimens have been shocked in the pressure region of 130-400 kbars.

In all four specimens of Elbogen investigated the kamacite appeared to be completely recrystallized (Fig. 3a). The plessite grains were relatively clear and both taenite and plessite grains showed "thorny" edges, indicating nickel diffusion. While most phosphide inclusions were somewhat corroded, it could still be observed that the phosphide was dissolving into the kamacite matrix. In one specimen we observed a relict shear region which traversed kamacite, taenite and plessite but which had been subsequently recrystallized.

All the observations<sup>2,9</sup> suggest that every Elbogen specimen investigated has been reheated (either by shock or annealing) to  $700^\circ \pm 50^\circ \text{C}$  for a period of up to a few days. X-ray diffraction photographs of a number of Elbogen kamacite grains indicated randomly oriented polycrystalline aggregates. Such features, however, are apparent in both annealed and shock-recrystallized kamacite<sup>4</sup>. Schreibersite grains yielded typical single-crystal diffraction patterns (Fig. 3b) similar to those of unshocked meteorites (Fig. 3c), both unheated and annealed. Diffraction patterns of schreibersite from an Odessa specimen artificially shocked to 800 kbars (the pressure required to recrystallize kamacite) showed preferred orientation, however (Fig. 3d). It appears therefore that Elbogen kamacite was recrystallized by annealing rather than by shock-associated high temperatures.

Table 1

Meteorite (recovered mass in kg)	Source (specimen number)	Date found
Coopertown (17)	CNHM (Me 1126) Yale (P 231)	(fell) 1860
Elbogen (107)	BMNH (1922, 162: 90219) Yale (M 220: P 7)	1860 (1400)
Magura (1,500)	BMNH (33025: 19101 c) CNHM (Me 888)	1840
Narrabura (32)	Yale (M 288: M 307: P 18a) CNHM (Me 1142)	1855
Spearman (10)	CNHM (Me 2218)	1934

BMNH—British Museum (Natural History). CNHM—Chicago Natural History Museum. Yale—Bosch and Peabody Collections.

Of the meteorites which we have investigated, four seem to have been shocked to pressures of 130–600 kbars at some time during their history. It is impossible to say whether the shock(s) occurred preterrestrially or during impact with the Earth. The small masses of the recovered meteorites (Table 1) and their lack of association with terrestrial explosion craters would suggest, however, that the former alternative is the more likely. For these four cases, then, it seems that the abnormal diffraction features are strongly indicative of a severe shock.

Fig. 1. Microstructure of Odessa meteorites shocked artificially to (a) 200, (b) 400 and (c) 600 kbars. Note the localized nature of the  $\epsilon$ -iron transformation structure at 200 kbars. The textural differences permit estimation of peak shock pressures in naturally shocked iron meteorites. Scale bars are 0.1 mm.

Fig. 2. Photomicrographs showing microstructure of Narrabura (a), Coopertown (b) and Magura (c) iron meteorites. Apparently Magura has been shocked to 130–400 kbars; Narrabura (and Spearman) to 400–600 kbars; and Coopertown to 600 kbars.

Our observations on Elbogen would suggest that its recrystallization was caused by annealing at low pressures rather than by shock. This conclusion does not, however, explain the observation<sup>6</sup> of Elbogen's kamacite having preferred orientation covering  $40^{\circ}$ – $50^{\circ}$  of arc. We have observed that such arc segments can be obtained by incompletely etching a randomly oriented polycrystalline kamacite aggregate<sup>4</sup>. It would therefore seem either that Leonhardt's Elbogen sample was improperly prepared or that true shock alterations were not distributed uniformly throughout the meteoroid. Until it can be demonstrated

Fig. 3. Microstructure of the Elbogen meteorite (a) showing thermal alteration effects. X-ray diffraction photographs (manganese-filtered iron  $K\alpha$  radiation) of unrotated single grains of schreibersite ( $\text{Fe}_3\text{P}$ ) from: (b) Elbogen, (c) unshocked Odessa specimen, and (d) Odessa sample artificially shocked to 800 kbars. The diffraction photographs indicate that Elbogen specimens have not been shocked to high pressures at any time during their history.

that specimens of Elbogen have been shocked we feel justified in considering it to be an unshocked, thermally altered meteorite.

Our observations and those of Leonhardt<sup>5</sup> and Short and Andersen<sup>6</sup> on sixteen randomly chosen specimens suggests that shock effects in iron meteorites are not rare. If we eliminate Elbogen from consideration, eight of the fifteen

meteorites have been shocked to pressures in excess of 130 kbars. Although the number of meteorites investigated is small, it is large enough to indicate that, at the 95 per cent confidence level, at least 7 per cent of the known iron meteorites (nearly 600) should have been severely shocked at some time during their history. One additional significant point should be raised in this connexion. After completion of our study, it was brought to our attention that the  $\epsilon$ -iron transformation structures in Magura and Narrabura had been reported previously<sup>10</sup>. Furthermore, Buchwald<sup>10</sup> has observed it also in two other meteorites, Treysa and Bella Roca. It is important to note that most of the small shocked meteorites reported here and elsewhere<sup>1,5,6,10</sup> belong to the Ga-Ge group III as we will discuss in a forthcoming publication.

We conclude by considering the occurrence of diamond<sup>7</sup> in the Magura meteorite. In a previous paper<sup>2</sup> we reported that one Magura specimen showed evidence for shock-induced recrystallization of kamacite, while two others did not. A re-examination of one of these two and examination of five other Magura specimens showed that the  $\epsilon$ -iron transformation structure was invariably present, indicating a minimum shock pressure of 130 kbars. Recent work by De Carli has shown that diamond can be formed from graphite by shock pressures as low as 100 kbars. Unfortunately all the specimens of Magura which we investigated were devoid of troilite ( $\text{FeS}$ )-graphite nodules, so that no diamonds could be expected. In view of Magura's shock history, however, it seems quite possible that some specimens may indeed contain diamonds. Because many meteorites seem to have been shocked, a search for diamond among these might be expected to yield positive results.

This research was supported by grants from the U.S. National Aeronautics and Space Administration and the Advanced Research Projects Agency. We thank Dr. M. H. Hey, Dr. E. Olsen and Professor K. K. Turekian for the loan of the meteorite specimens.

## Variations in the Flux Density of Some Quasi-stellar Sources

by  
K. I. KELLERMANN  
I. I. K. PAULINY-TOTH

National Radio Astronomy Observatory,\*  
Green Bank, West Virginia

Further data on the variations in the 1.96 cm flux density of the quasars 3C 273, 3C 279, 3C 446 and 3C 454-3 are reported. The data support the theory that the variation is produced by repeated injection into magnetic field of clouds of relativistic electrons, which then expand, but some difficulties remain.

DURING 1966, periodic observations of the variable quasi-stellar sources 3C 273, 3C 279, 3C 446 and 3C 454-3 have been made at a frequency of 15.3 Gc/s (1.96 cm) in order to determine accurately the nature of their time variations. Previous observations of 3C 273 and 3C 279 at 2 cm and at longer wavelengths had shown that significant

variations occur with time scales of a few months or less<sup>1</sup> (Allen, R., and Dent, W. A., communicated at the Union Radio-Scientifique Internationale Spring Meeting, Washington, D.C., April 18-21, 1966, and Pauliny-Toth, I. I. K., and Kellermann, K. I., communicated at the 121st meeting of the American Astronomical Society, Hampton, Va., March 28-31, 1966.) It has been suggested<sup>1</sup>, on the basis of the wavelength dependence of the variations and

Fig. 1. The flux density of 3C 273 and 3C 279. The observations of the U.S. National Radio Astronomy Observatory are shown as solid circles and the error bars represent the relative accuracy of measurements made at different epochs. The measurements of Dent at 1.8 cm are shown as open circles and the error bars for these represent the absolute accuracy.

the form of the radio spectra, that these variations are caused by repeated injection into a magnetic field of a dense cloud of relativistic electrons. This cloud is initially optically thick to synchrotron radiation at centimetre or even millimetre wavelengths. Expansion of the cloud causes it to become optically thin at successively longer wavelengths. In the region where the cloud is optically thick, the flux density increases with time, while it decreases at frequencies where the cloud is optically thin.

In this communication we present the results of observations made in June, August–September, and December 1966, and compare them with earlier measurements made in October 1965 and February–March 1966. All of the observations were made with the 140-ft. radio telescope at the National Radio Astronomy Observatory. During the first observing period, the radiometer consisted of a crystal mixer which gave a system noise temperature of about 500° K and a bandwidth of 10 Mc/s. In all of the following periods, this was replaced by a tuned radio frequency tunnel diode radiometer having a system noise temperature of 1,200° K and a bandwidth of 2 Gc/s. In order to reduce the effect of atmospheric fluctuations, the radiometer was switched between the main beam, directed along the electrical axis of the paraboloid and an offset reference beam 6.5 minutes of arc (about 3 half-power beamwidths) away<sup>2</sup>.

In each observing period, a number of other sources of small angular diameter were observed as calibrators. Two or more of the stronger sources were also observed over a large range of hour angles in order to determine the variation of the aperture efficiency of the telescope and of the atmospheric extinction as a function of the antenna orientation. To within an accuracy of 5–10 per cent the aperture efficiency was found to be a function of the zenith angle alone up to a zenith angle of about 50°. At this point the antenna temperature of a point source falls to about half of its value at the zenith, partly as a result of the decrease in aperture efficiency and partly because of the increased atmospheric extinction\*.

Nearly all the observations were made within 30 min of meridian transit and the known change of the telescope gain with hour angle was used to correct the measurements to the meridian. Each observation consisted of a measurement of the ratio of the antenna temperature to a calibration signal from a gas discharge tube. For the stronger sources, the antenna beam was first positioned roughly on the source, the feed horn was then focused for maximum

antenna temperature, and the antenna beam was positioned on the source with an accuracy better than 6 sec of arc (0.05 of the half-power beamwidth). A measurement of the antenna temperature of the source relative to the calibration signal was then made by pointing the beam first towards the source and then towards a reference point about 1 min away in right ascension. For weaker sources, on which the antenna could not be positioned accurately, a series of on-off measurements was carried out not only at the expected position of the source but also at each of four positions about 1 min of arc away in right ascension or declination. A two-dimensional gaussian distribution curve was then fitted to the five measurements to determine the true antenna temperature of the source. Each observation was made in two orthogonal polarizations, so that the total flux density, including any linearly polarized component, could be determined.

The sensitivity and stability of the tunnel diode radiometer were such that the uncertainty caused by the receiver noise in a single on-off measurement was a few tenths of a flux unit (1 flux unit =  $10^{-26}$  W/m<sup>2</sup>/(c/s)). For the weaker sources, this uncertainty was reduced to about one tenth of a flux unit or less by repeating the on-off measurements. With the exception of the observations in October 1965, the day-to-day scatter in the relative antenna temperatures during a single observing period was of the order of 2–3 per cent for the stronger sources 3C 273, 3C 279, 3C 454.3, Virgo A and Jupiter. Observations made at different periods were related by expressing all the results as ratios to Virgo A. Measurements of the planets Jupiter and Saturn, the planetary nebula NGC 7027 and the non-thermal source 3C 123 showed that the flux density of Virgo A remained constant within 3 per cent over the period February 1966 to December 1966, and that it was the same to within 10 per cent in October 1965.

In October 1965, the accuracy of the measurements was determined mainly by the receiver noise and amounted to 2–3 flux units. In 1966, for any one of the sources 3C 273, 3C 279, and 3C 454.3, the accuracy with which the relative flux density at different times could be determined was not limited by the receiver noise, but by other effects, such as variations of the gain of the antenna, of the atmospheric extinction or of the calibration signal, or by uncertainties in the pointing of the telescope and in the focusing of the feed horn. All these amounted to an uncertainty of about 2 per cent. For 3C 446, the accuracy was about 0.1 flux units and was limited by the receiver noise. The relative flux densities of sources at different declinations measured during the same period are less certain because of the uncertainty of about 5 per cent in the variation of the gain of the antenna with its orientation. The scale of flux density is based on

Fig. 2. The flux density of 3C 454.3. The error bars represent the relative accuracy of measurements made at different epochs.

\* Measurements made on more extended sources such as Cas A and Cyg A, which have angular sizes comparable with the beamwidth, indicate that the beam efficiency is much less dependent on the zenith angle than the aperture efficiency, as determined from the measurements of "point" sources.

observations of Virgo A, Hydra A and 3C 161, the flux densities of which at 2 cm were estimated to be 28, 4.6 and 2.6 flux units respectively from an extrapolation of their spectra at lower frequencies. It is thought that this scale is accurate to within 15 per cent.

The measured flux densities for the variable sources are given in Table 1 together with the epochs of the observations. The values for 3C 273 and 3C 279 are plotted in Fig. 1 together with those of Dent at 1.8 cm (communicated by Dent, W. A., Conference on Observational Aspects of Cosmology, Miami, Florida, December 15-17, 1965). The flux density of 3C 279, which showed a rapid increase at the beginning of 1966, has remained almost constant since April 1966, while the flux density of 3C 273 reached a broad maximum in June 1966, and has now begun to decrease. The flux density of 3C 454-3, shown in Fig. 2, began to increase in February 1966 and approximately doubled by September 1966. The peak was apparently reached sometime in October or November 1966. Previous observations at 20 cm (ref. 1) had suggested that this source is variable. The flux density of the source 3C 446 has increased by nearly 50 per cent during 1966 as is shown in Fig. 3. (*Note added in proof.* Measurements made during January 12-15, 1967, give the following flux densities:

3C 273	3C 279	3C 446	3C 454-3
58.9	23.7	4.63	28.1

There is thus evidence for renewed activity in 3C 279 and 3C 454-3.)

Table 1. OBSERVED FLUX DENSITIES\* FOR VARIABLE SOURCES

Epoch/Source	3C 273	3C 279	3C 446	3C 454-3
Oct. 1-5, 1965	41	8		12.3
Feb. 19-28, 1966	51.8	18.3		12.8
Mar. 3-15, 1966	54.9	19.3	3.29†	
Mar. 16-24, 1966	58.3	20.0		13.8
June 24-26, 1966	66.5	21.0	3.89	17.2
Aug. 21-30, 1966	64.9	21.2	4.12	22.9
Dec. 1-4, 1966	60.0	20.4	4.76	23.8

\* In flux units. For any one of the sources 3C 273, 3C 279 and 454-3, the random errors in the flux densities are estimated to be 2 to 3 flux units for the first period and 2 to 3 per cent thereafter, while for 3C 446 this error is 0.1 flux units. The absolute scale of flux densities is thought to be accurate to 15 per cent.

† Measured on March 11.

For a uniform, optically thick source expanding at a constant rate, the flux density increases approximately as  $t^3$  and the wavelength at which the optical depth is unity varies as  $t^2$  (ref. 1). The flux density at any frequency will be observed to increase when an appreciable fraction of the total flux is contributed by the expanding, optically thick component. The flux density will continue to increase until the expanding component becomes optically thin, at which time it will begin to decrease. Van der Laan<sup>3</sup> has given a more detailed mathematical description of this model and has shown that if the

Fig. 3. The flux density of 3C 446. The error bars represent the relative accuracy of measurements made at different epochs.

Fig. 4. The epoch at which the flux density of 3C 273 is expected to reach its maximum at different wavelengths, according to the simple model of a uniformly expanding source.

maximum flux density reached at frequency  $f_1$  is  $S_1$  then the maximum at frequency  $f_2$  is

$$S_2 = S_1 (f_2/f_1)^{5-7\alpha/5-4\alpha} \quad (1)$$

where  $\alpha$  is the radio spectral index in the range of frequencies where the source is optically thin. Thus, a detailed measurement of the variation at one frequency can in principle be used to predict the variations at any lower frequency.

The actual situation, however, is more complex because of the simultaneous presence of several components at different states of evolution. Although at any one frequency the spectrum may be dominated by a single strong component of increasing flux, there may remain an older and weaker component with a decreasing flux density. This makes the determination of the flux density of the main variable component and its rate of change more difficult. In 3C 273, for example, at least three components can be recognized<sup>1</sup>. From the form of the radio spectrum and from the rate of increase of the flux density at 2 cm in the spring of 1966, we estimate a characteristic age for the strong 2 cm component of about 1.3 yr in April 1966, when the flux reached a maximum at 2 cm. The epoch at which the flux density will reach a maximum at longer wavelengths has been estimated from the characteristic age and the relation

$$t(f_2) = t(f_1) \left( \frac{f_2}{f_1} \right)^{1/2} \quad (2)$$

and is shown in Fig. 4. A similar age is found for 3C 279 in the early spring of 1966 when the maximum flux was reached at 2 cm. The corresponding maxima at 3.75 and 6 cm are expected in late 1966 and early 1967 respectively.

The simple model predicts that the flux will begin to decrease after the maximum is reached at a rate which depends on the radio spectral index<sup>1,3</sup>. Inspection of Fig. 1 shows that this is clearly not the case for 3C 279 where the flux density has remained at a high level for six months. A possible explanation is that the density of relativistic particles increases towards the centre of the source, so that the inner region is still optically thick at a time when the outer parts are becoming optically thin. Such a gradient in the density of particles could occur if their production took place over a period of time, rather than in a short burst at the beginning of the expansion.

For 3C 454-3, the characteristic age derived from the rate of increase of the flux density at 2 cm is 1.2 yr for the epoch August 1966 when the maximum was reached at this wavelength. The most recent observations indicate that this component started to become optically thin at 2 cm shortly after the middle of 1966. In May 1966, when this component was still optically thick at 2 cm, its flux density at that wavelength was about 13 flux

units and at longer wavelengths its contribution should have been

$$S_{\lambda} \sim 13 \left( \frac{2}{\lambda_{\text{cm}}} \right)^{2.5} \quad (3)$$

This corresponds to an increase of about 2.7 flux units at a wavelength of 3.75 cm and of about 1 flux unit at 6 cm for the variable component—a change in flux density that should be easily detectable. The maxima at 3.75 and 6 cm are expected to occur in early and late 1967 respectively, and the corresponding maximum flux densities from equation (1) should be about 6.5 and 4 flux units (for  $\alpha = -0.2$ ).

Although the number of sources discussed here and the time span over which the observations have been made are limited, a few comments can be made about the general nature of the variations. First, the qualitative form of the variations differs somewhat from source to source. Second, the time scales for variations at 2 cm are considerably less than 1 yr. Third, if the sources are at the cosmological distances indicated by their red-shifts, the absolute monochromatic power radiated at 2 cm has increased by  $10^{27}$  W (c/s) for 3C 273 to  $10^{28}$  W (c/s) for 3C 454.3. The latter value is based on a red-shift of 0.87 obtained by Lynds (private communication). The change in the total radiated power is uncertain because of the lack of spectral data at shorter wavelengths but it is certainly greater than  $10^{45}$  ergs/sec for 3C 454.3, and not less than  $10^{44}$  ergs/sec for 3C 273 and 3C 279. This is equivalent to the creation of a radio source as intense as the most powerful radio galaxies such as Cygnus A or 3C 295 in a time interval of 6 months. Similarly, the energy requirements involve the production, in a time of a few months and in a volume of space smaller than 1 pc,

of relativistic particles with a total energy comparable with that found in the strong radio galaxies. Rees<sup>4</sup> has suggested, however, that the actual time scales may be longer than the observed values if the source is expanding with a velocity near that of light.

It might be expected that such a violent event would be observable at optical wavelengths and that the "light flashes" observed in the quasistellar sources may represent this explosion. At least in the case of 3C 273 no change greater than 0.07 magnitudes has been reported during the past two years<sup>5</sup>, although, of course, no optical observations are available for mid-1965 when the event possibly occurred, because the source was near the Sun at that time. In the case of 3C 279 (ref. 6) and 3C 454.3 (ref. 5), significant variations have occurred sometime between 1950 and 1966. In 3C 446 changes of as much as three magnitudes have been observed during the past year<sup>7</sup> and it will be of interest to see if the 2 cm flux increases more rapidly during the next year. On the other hand, there are several sources such as 3C 48 and 3C 196 which are known to be variable at optical wavelengths<sup>8</sup> but for which no radio variations have yet been detected. Clearly, more or less simultaneous observations are needed at radio and at optical wavelengths to determine if the intensity variations at the two wavelengths are at all correlated, or if they are caused by different mechanisms.

## Altithermal Timberline Advance in Western United States

by

A combination of radiocarbon dating and counting of annual rings of the remains of trees has been used to establish the time of retreat of forests from sub-alpine mountains in California and Nevada. The information obtained can serve as a palaeoclimatic indicator.

THE position of the mid-latitude alpine timberline may be a sensitive climatic indicator. Evidence from widely separated localities in California and Nevada shows that a rise and later recession of timberline have occurred during the past several thousand years, in agreement with other indications of a postglacial "thermal maximum". Dead trees and large fallen remnants occur on mountain slopes above the highest living "timber-sized" trees in the White Mountains, California, and in the Snake Range, Nevada (Fig. 1). The dominant sub-alpine tree in the White Mountains is the bristlecone pine (*Pinus aristata* Eng.), which is accompanied by limber pine (*P. flexilis* James)<sup>1</sup>. Engelmann spruce (*Picea engelmannii* Parry) is the typical timberline tree in the Snake Range, but bristlecone and limber pine are locally abundant. In both localities, the remnants appear to be those of bristlecone pines. Exposed wood of trees of this species can persist for several thousand years<sup>2</sup>, and thus can provide direct evidence of the former distribution of trees.

The discontinuity of the sub-alpine forest means that a climatic timberline exists only locally in the White Mountains. It is clearly defined where the upper limit of a wooded area coincides with topographic contours.

Extensive unwooded tracts below timberline correspond to areas of unfavourable sandstone, shale or granite<sup>3</sup>. Timberline is highest on the dolomite that makes up the east slope of Sheep Mountain (Fig. 1). It is lower on sandstone areas such as Campito Mountain and County Line Hill. Despite the differences in absolute altitude of timberline on different rock-types, the highest remnants have been found at similar vertical distances above timberline on both dolomite and shale. In each case tree remnants are most abundant near the present timberline and include numerous dead, but still erect, trees. Only the greatly reduced and deeply weathered remains of fallen trees occur at the higher altitudes at each locality.

Fire or other catastrophic agencies cannot be responsible for the occurrence of tree remnants through comparable altitudinal ranges above timberline on several isolated peaks. The low density of trees and the sparsity of litter and flammable ground-cover preclude widespread burning of the sub-alpine forest near timberline. Although a few of the remnants have been charred, local fires caused by lightning are probably responsible. A number of factors may have contributed to the death of individual trees above timberline, but only a climatic change seems

to explain adequately the absence of living trees on these once-wooded summits.

The present position of a dead tree or large remnant marks the lowest possible altitude of timberline during the lifetime of the tree. Dating of these remains, therefore, establishes the minimum timberline altitude in the past. Radiocarbon age determinations were made of samples from the wood of four tree remnants in the White Mountains, and from three in the Snake Range (Table 1). In addition, the number of years of growth represented by the wood of the entire specimen was determined by counting annual rings exposed in a supplementary transverse section or increment core. Because the chronological position of the radiocarbon sample relative to the ring-count is known, the approximate dates of the earliest—and latest—formed growth increments present in the specimen can be determined.

Table 1. AGE AND ALTITUDE DATA FOR TREE REMNANTS ABOVE MODERN TIMBERLINE

Specimen	Altitude (m)	Age data ring count (yr before present)					
Map No.	Field designation	Above sea level	Above timberline	Approx.	From		Radiocarbon date
				date of estab-lishment	Inner ring	Outer ring	
White Mountains, California							
1	202	3,480	120	3,100	2,663	789	840 ± 80 (UCLA-1070F)
2	195	3,490	130	3,200	3,193	2,367	2,540 ± 80 (UCLA-1070B)
3	382	3,510	150	4,300	4,214	3,501	3,565 ± 80 (UCLA-1070G)
4	231	3,360	120	5,800	4,507	3,784	4,000 ± 80 (UCLA-1070A)
Snake Range, Nevada							
—	362	3,540	120	2,488 ± 2,488	2,003	2,350 ± 80 (UCLA-1070C)	
—	364	3,540	120	3,049 ± 3,049	2,028	2,240 ± 80 (UCLA-1070D)	
—	363	3,540	120	4,017 ± 4,017	2,627	3,930 ± 80 (LJ-1336)	

Weathering and decay have destroyed the early formed wood in most of the specimens. The date of establishment of the tree, therefore, can only be estimated. The time-span represented by the missing inner wood is obtained by combining the probable amount of radial growth missing with the probable average growth rate during the period. The original location of the stem

axis is estimated by projection of intact radial branches or the radii of curvature of concentric growth-rings. The average growth rate indicated by the innermost few inches of remaining wood is inferred to equal that in the missing portion. The resulting figure is added to the age of the innermost remaining ring to give the estimated date of establishment. This is listed in Table 1 for those specimens in which evidence of the original size and form of the tree is sufficiently well preserved.

Ranking of tree remnants in the White Mountains according to position shows that the time that has elapsed since death increases progressively with increasing altitude of the site (Table 1). Except that the two highest remnants are also the oldest so far discovered at each locality (2 and 4 on map, Fig. 1) there is no consistent pattern of ages with respect to altitude above local timberline. The times of death of two specimens (1 and 2 on map) representing the highest dead, but still erect, trees on Campito Mountain differ by 1,500 yr. The younger of these is 120 m above timberline, but died only 750 yr ago. The fact that both trees were established at about the same time, at similar altitudes, suggests that certain trees can survive in conditions that contribute to the death of less favourably situated specimens, and that preclude the establishment of seedlings. Thus, where long lived trees such as bristlecone pine are involved, changes in the position of timberline defined by the highest living trees may lag several hundred years behind changing environmental conditions. The time of establishment of individual trees seems to be of greater significance than the time of their death as an indicator of past environmental conditions. The four dated remnants from the White Mountains were established at altitudes 120–150 m above present timberline before about 3,000 yr ago. We conclude that the onset of adverse conditions has occurred since that time.

The existence of a similar "fossil timberline" in eastern Nevada, about 400 km north-east of the White Mountains, suggests that a net retreat of the upper forest limits in the past few thousand years is a phenomenon of at least regional extent. On the south slope of Mount Washington (altitude 3,460 m), near the centre of the Snake Range, Nevada, bristlecone pine forms a timberline at an altitude of 3,420 m. Although scattered clumps of Engelmann spruce and bristlecone pine krummholz reach nearly to the summit, no large, erect trees are now living above timberline. Large wood fragments, however, are abundant on the slope up to 3,540 m. One of these (364) listed in Table 1 is more than 2 m long. A total of 1,030 annual rings was counted along the measured 67 cm radius. Because the prostrate stems of the dwarfed krummholz forms reach only a few centimetres in diameter, this is clearly the weathered remnant of a large tree similar to those now living at much lower altitudes. No date of establishment was estimated for any of the three dated specimens, because their original form cannot be confidently inferred. They were all, however, established about 2,500 yr ago, and all died within the same period, between 2,000 and 2,700 yr ago.

Alpine timberline may fluctuate in response to long term temperature trends. In north temperate latitudes, the position of the timberline seems closely associated with the altitude at which the near July temperature is about 50° F. (refs. 4 and 5). Climatic cooling would lower this apparent altitudinal limit. Thus interpreted, evidence of timberline retreat within the past several thousand years can be compared with other palaeoclimatic indicators. An extended period of higher than present temperatures, variously termed the Climatic Optimum, Hypsithermal, or Altithermal, has been widely recognized. It followed the cold period of the Late Wisconsin glacial maximum, when montane life-zones were presumably depressed far below present altitudes. Antevs<sup>6</sup> originally considered the Altithermal to have lasted from about 7,000 to 4,000 yr ago in the western United States, and

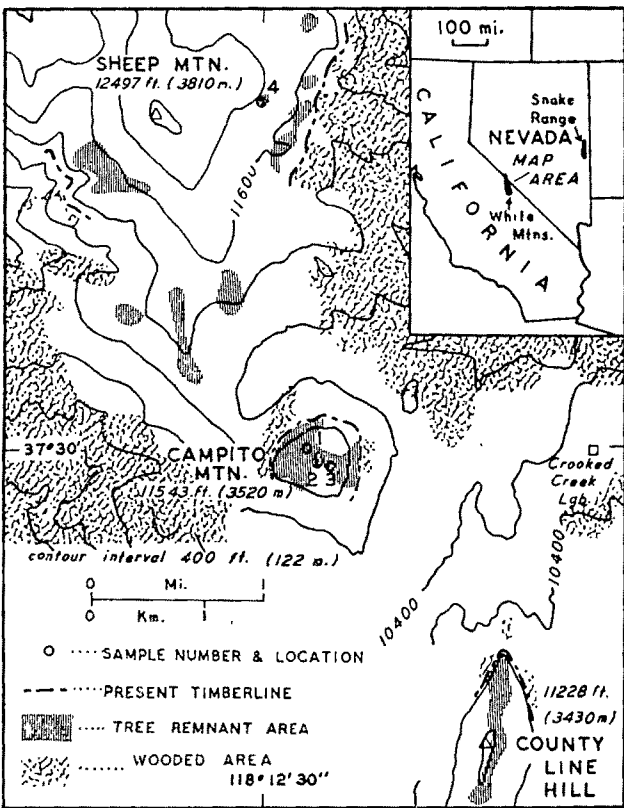

Fig. 1. Generalized topographic map of southern White Mountains, California, showing distribution of tree remnants above modern timberline.

to have ended with the reappearance or readvance of alpine glaciers of the "little ice age" of Matthes<sup>7</sup>. More recent work has shown that this widespread glacial readvance occurred between 2,600 and 2,800 yr ago at many localities in western North America<sup>8</sup>. At about the same time, our evidence shows that reproduction of bristlecone pine ceased near what was then the upper forest margin. Timberline retreated erratically with the death of individual trees that had been previously established. We conclude that the shrinkage or disappearance of alpine glaciers in Altithermal time was accompanied by an upward advance of sub-alpine forests to altitudes at least 150 m above the present timberline, and that timberline retreat began at the time of renewed glacial activity of the "little ice age", in response to climatic cooling. Although its retreat to present levels may have been punctuated by long periods of comparative stability,

or even by significant readvances, alpine timberline in the western United States rose to maximum post glacial height in Altithermal time.

Dimethyl sulphoxide decreases the viability of HeLa cells actively metabolizing in tissue culture. It inhibits attenuated virus strains more strongly than virulent strains, but seems to have little effect on the rate of virus adsorption.

THE penetration of a variety of topical pharmaceuticals is dramatically improved when they are used in conjunction with dimethyl sulphoxide (DMSO) (ref. 1). As a vehicle, DMSO could conceivably enhance the penetration of viruses *in vivo* as well as *in vitro* and possibly allow the crossing of species barriers. We have found that DMSO administered with the virus did not alter the number of passages required to adapt an egg-passed influenza virus strain to C57BL6J mice. In addition, intranasal inoculation of 3–5 per cent DMSO had no readily apparent adverse effects on the animals. These observations, coupled with the ability of dimethyl sulphoxide to protect cells during freezing<sup>2</sup>, suggested that further information about the biological properties of DMSO was necessary. This investigation therefore consists of a series of observations dealing with the influence of DMSO before and during viral penetration and synthesis.

The clone of Gey HeLa cells used in these studies was obtained from the University of Michigan, where it was given the name HCAAT. These cells were propagated as suspension cultures in a medium free from antibiotics consisting of 2X Eagle's vitamins, amino-acids and glutamine, 10 per cent calf serum, 15 per cent tryptose phosphate, 2 per cent sodium citrate, 0.12 per cent methylcellulose, suspended in Hanks balanced salt solution (BSS). For plaque assay of poliovirus, 4 ml. of cells at a concentration of  $7.5 \times 10^5$  cells/ml. were suspended in the medium without methylcellulose and sodium citrate and introduced into 2 oz. tablet bottles. The cells were incubated for 24 h at 34° C, and the monolayers thus formed were washed twice with Hanks BSS. These cells were then infected with the appropriate dilutions of poliovirus, incubated for 30 min at 34° C with gentle bottle agitation, and overlaid with 3 ml. of 1 per cent

agar consisting of monolayer growth medium (less calf serum and phenol red) containing 100 U of penicillin and 100 µg of streptomycin per ml. In certain experiments various concentrations of DMSO were incorporated either into the suspension culture medium or the agar overlay. After incubation at 34° C for 72 h the plaque bottles were further overlaid with 3 ml. of 1 per cent agar in Hanks BSS and 1 : 20,000 neutral red; the plaque counts were performed 12 h later.

In those experiments where cell viability was studied, the erythrocin B dye exclusion technique<sup>3</sup> was used. Cloning efficiency could not be measured because of the relatively poor attachment characteristics of the HCAAT cell line. The cells were sized using an electronic cell counter and cell size analyser.

Nucleoside incorporation was analysed by a method previously described by Bollum<sup>4</sup> and modified for tissue culture studies by Regan and Chu<sup>5</sup>. This was undertaken in an effort to determine the influence of different concentrations of DMSO on cellular nucleic acid metabolism. At various intervals after exposure to DMSO, 1 ml. quantities of suspension-culture HCAAT cells were pipetted into 5-ml. plastic test tubes. 0.1 ml. of fresh suspension culture medium containing 2–5 µc. of tritiated thymidine (approximately 2 c./mmole) or 2–5 µc. tritiated uridine (approximately 0.825 c./mmole) was added. The tubes were mixed well, incubated for 30 min at 37° C, and then placed in an ice bath. The cells were then lysed in an oscillator and 100 µl. of the sample was applied to a disk of filter paper 2.3 cm in diameter. After adsorption for 1 min the disk was submerged in 5 per cent trichloroacetic acid at 4° C. When the experiment was completed, all the disks were washed three times for 10 min in cold 5 per cent trichloroacetic acid, three times for 10 min in 95 per cent ethanol at room temperature, and twice rapidly in ether. The disks were dried com-

pletely after each submersion. They were then placed in glass scintillation vials containing 5 ml. of 2,5-diphenyl-oxazole and 1,4-bis-2-(4-methyl-5-phenyloxazolyl) benzene in toluene, and counted in a liquid-scintillation spectrometer.

The toxic effects of various concentrations of DMSO on HeLa cell suspension cultures, using the morphological criteria of cell viability and cell size, are indicated in Table 1 and Fig. 1, respectively. Cell viability decreases rapidly after exposure of the cell population to concentrations of DMSO greater than 1 per cent for periods greater than 12 h. This decrease in cell viability is further shown by an increase in the number of smaller cells (indicated by the shift of the cell population to the left in Fig. 1). The rapidity of this sequence of events depends on the concentration of DMSO to which the cell population is exposed.

Changes in cellular metabolism due to exposure to several low concentrations of DMSO are illustrated in Figs. 2 and 3. The rate of nucleoside incorporation (uridine and thymidine) is rapidly altered as the cell population is exposed to DMSO incorporated in the growth medium. Uridine and thymidine incorporation are proportionately affected by increasing concentrations of DMSO. There is a lag in the incorporation of uridine at the 1, 2 and 3 per cent DMSO concentrations. This delay in incorporation is partially overcome at 24 h. With 4 per cent DMSO this lack of incorporation is irreversible. There is an apparent depression of thymidine uptake after the first 24 h of exposure to DMSO; this depression is proportional to the concentration of DMSO. Decreased incorporation at the 1 per cent level is overcome during the next 12 h.

The influence of several concentrations of DMSO on the competence of HeLa cells in the synthesis of polioviruses was considered another criterion of cellular integrity. Depending on the concentration of DMSO incorporated into the agar overlay of plaque bottles after viral adsorption for 30 min, it was possible to differentiate

Fig. 1. Cell size distribution of HeLa cells exposed for 24 h to 0-4 per cent DMSO (each window is equal to a cell volume of  $240 \mu^3$ , and cell volume is therefore equal to  $240 \mu^3 \times$  window number).

Fig. 2. Incorporation of tritiated uridine into HeLa cells treated with DMSO and propagated in suspension culture.

Fig. 3. Incorporation of tritiated thymidine in HeLa cells treated with DMSO and propagated in suspension culture.

between the attenuated and virulent strains of poliovirus (Fig. 4). In all cases, the attenuated strains were more adversely affected than the virulent strains, with the Sabin Type I strain (PLS) and the Mahoney strain (PLM), respectively, being the most competent in replication. To determine whether these results were due to direct inactivation of the virus by DMSO, we incubated the Mahoney and Sabin I strains for 24 h at  $4^\circ \text{C}$  in the presence of concentrations of DMSO ranging from 1 to 100 per cent. At concentrations of DMSO greater than 65 per cent no virus could be detected (Table 2). The observations in Fig. 4, therefore, cannot be due to viral inactivation but are probably due to effects of DMSO on the cell. Fig. 5 shows one such indication of a cytotoxic effect—the effect of DMSO on doubling time of exposed cells.

Fig. 4. Effect of various concentrations of DMSO on the selective P.F.U. inhibition of attenuated (PIS, PIIS, PIIS) and virulent (Mahoney (PIM), MEF, Salk) polioviruses.

To determine further the particular stage of viral propagation affected by DMSO, we studied the interim period between viral adsorption and viral release. We were unable to demonstrate a significant influence of 3 and 4 per cent DMSO during the first hour of virus adsorption (see Table 3).

Because none of these observations answered attenuated/virulent virus selectivity by DMSO, we believed these results could possibly be explained on the basis of elongation of the eclipse phase. As seen in Figs. 6 and 7, using a virus multiplicity of 20, virus release in the virulent strain begins 1 h before that in the attenuated strain; moreover, the peak virus yield is attained at least 1–2 h before that of the attenuated strain. A concentration of 3 per cent DMSO somewhat inhibits total virus yield in both strains, though appreciably more so in the attenuated strain. Similarly, DMSO has an appreciable sparing action with regard to loss of cell viability as determined by dye exclusion. Cells

exposed to virus alone lose their viability more rapidly than cells exposed to virus and DMSO.

We have been able to confirm a previous report<sup>6</sup> which indicated that, after 24 h association, concentrations of DMSO above 1.5 per cent are inhibitory to cell replication. The cytotoxic effects of 2, 3 and 4 per cent DMSO can be demonstrated after as little as 12 h using the criterion of vital stain exclusion. We are able to demonstrate that DMSO delays nucleoside incorporation; this can be observed as early as 12–24 h after the addition of 1 per cent DMSO to a cell population. The fact that, with the 1 per cent DMSO, both uridine incorporation and thymidine incorporation are merely delayed may indicate certain compensating or detoxifying factors present in the cell or its environment. The labelled nucleoside pool may be influenced by DMSO. This was not, however, determined in the present study.

The influence of DMSO on viral synthesis, another criterion of cell competence, sheds still more light on the possible mode of action of DMSO. The observation that DMSO seems to have a selective effect, depending on concentration, between the attenuated and virulent strains of poliovirus may be due to a longer eclipse phase in the attenuated strain, which causes it to reach optimal viral yield at least 1 h after the virulent strain, even when a similar viral multiplicity is used. In view of the nucleoside incorporation, a delay in viral synthesis places at a distinct disadvantage the virus with a longer eclipse phase. Once more, one must consider that plaque forming units cannot be found macroscopically until approximately 48 h after virus adsorption. During this interval, 2, 3 and 4 per cent DMSO has inactivated more than 50 per cent of the cell population. It should also be mentioned that although up to 4.25 per cent DMSO was incorporated into the agar overlay, the quantity of DMSO to which the cells were exposed at any one time was lower due to diffusion of DMSO through the agar. Therefore, by the time DMSO demonstrates its maximum

inhibitory effects, the virulent virus has replicated to the point at which it has formed a visible plaque.

The optimum virus yield of DMSO-treated and untreated cells again indicates that DMSO in the virulent strain is inhibitory to about 50 per cent. The attenuated strain is inhibited by better than 95 per cent. We therefore propose that the selectivity of DMSO to the attenuated and virulent strains of poliovirus is associated with the influence of the compound on cell metabolism and is magnified by the difference in rate of virus synthesis. The sparing action of DMSO on cells infected with virus, as indicated by vital staining, can again be explained by the fact that virus infection and synthesis may bring about an alteration in cell permeability which in time may alter the capacity of the cells to exclude erythrocin B. In the presence of DMSO, virus synthesis is reduced, which eventually delays the cytotoxic consequences of viral infection. We have no evidence that DMSO increases

Fig. 6. Growth curve of Sabin Type I poliovirus in HeLa cells propagated in suspension culture. Cell viability estimated by erythrocin B dye exclusion.

the permeability of HeLa cells or the synthesis of poliovirus. Our results indicate that there is no difference in the rate of virus adsorption. Using low multiplicities of infection, we could find no increase in optimum virus yield. This again suggests that the sequence of events leading from virus adsorption to release and subsequent adsorption is not enhanced by DMSO. If anything, DMSO decreases optimum viral yield.

## Glucose Binding by Homogenates of Intestinal Mucosa

by

SHEILA M. FERNIE

S. L. HART\*

J. A. NISSIM†

Department of Pharmacology,  
Guy's Hospital Medical School,  
London

Glucose binds to soluble material in homogenates of intestinal mucosa; the degree of binding is dependent on pH and is increased by drugs which block glucose absorption.

In 1964 a new theory of the mechanism of intestinal absorption was proposed, a theory which was developed from the elucidation of the blocking actions of phloridzin and of cetrinide on the first and second receptors of intestinal sugar transport *in vivo*<sup>1,2</sup>. It was also shown that the mechanism of active transport involving the second receptor applies widely to nutrients other than

glucose and also to a number of species including man<sup>3,4</sup>. The results also indicated that the second receptor is situated on mobile intracellular proteins and that nutrients become associated with the protein on the luminal side of the cell and are released on the basal side. It was suggested that the dissociation constants between the nutrients and proteins are a function of the metabolic activities at the two opposite poles of the cell and the investigation of these proteins was thus the logical next

\* I.C.I. research fellow.

† Now deceased.

step in the further elucidation of the mechanism of absorption.

As a preliminary to such an investigation it was decided to find out whether glucose binding to intestinal mucosal homogenates could be demonstrated *in vitro* by simple techniques. Brief descriptions of the methods and a summary of the results obtained are given in this article.

Male albino rats, deprived of food overnight, were killed by a single blow on the head and immediately bled. The small intestines (except the distal 5 in.) were crushed using a pestle and mortar and the mucosa expelled by digital pressure along the length of the intestine. The mucosal tissue was collected and homogenized by further crushing with a pestle and mortar, or in an electrically driven homogenizer, and the volume measured. Usually about 7–8 ml. of tissue were obtained from three rats. After dilution four times in freshly gassed Krebs bicarbonate solution, 0.124 ml. of 65 per cent glucose solution in Krebs solution was added to each tube to bring the concentration of glucose to 200 mg per cent. This allowed for a mean contribution of 5 mg per cent from the intestinal mucosa, that is, of 40 mg per cent in the original undiluted tissues, this being the mean of thirty estimations by a modification of the method of Haslewood and Strookman<sup>5</sup>. By contrast, the value obtained using animals allowed free access to food was 95 mg per cent. The pH of the homogenate, measured using a glass electrode, was then adjusted to the required value by adding 0.1 normal sodium hydroxide or hydrochloric acid. As the volume of fluid added for adjustment of pH was less than 0.05 ml., corrections in glucose concentrations were neglected. After standing at room temperature for an average of 1.5 h the homogenate suspension was spun down at 12,000 r.p.m. for 30 min so that some of the bound glucose might go down with the protein. The supernatant fluid was again diluted with its own volume of Krebs buffer and the glucose content estimated by the specific glucose-oxidase method<sup>6</sup> in an auto-analyser. The readings were compared with control glucose estimations in Krebs buffer at the same concentration, so that the difference between the mean control value and the mean of any set of experiments would represent a measure of the glucose uptake by the mucosal homogenate.

Preliminary experiments were carried out at the pH of the homogenate (6.8–7.2). The mean of glucose readings after centrifuging, for eleven experiments on mucosal homogenates without added drug, was  $75.18 \pm 3.91$  mg per cent as compared with a control value of  $99.45 \pm 1.26$  mg per cent in Krebs solution. Because this difference is significant ( $P < 0.001$ ) it was concluded that glucose had been bound by the mucosal homogenate.

Because there was evidence that cetrимide, phloridzin and sodium lauryl sulphate blocked intestinal absorption by interfering with the glucose receptors<sup>1,2</sup>, the effect of these drugs on glucose uptake by the mucosal homogenates was next investigated. The drugs were dissolved in the Krebs solution before being added to the homogenate, to give concentrations of 0.1 per cent and 1.0 per cent. The results shown in Table 1 indicate clearly that only phloridzin was significantly effective in reducing uptake at the lower concentration, while all three were effective at the higher concentration. On the other hand, phloridzin had no greater effect at 1 per cent than at 0.1 per cent.

One property of the cell, which may vary within the cytoplasm, is the pH, and it was thought possible that a difference of pH between the two poles of the cell might explain the association and dissociation between nutrients

Fig. 1. Estimated concentration of glucose in the homogenate at various pH values in controls and in the presence of different concentrations of cetrимide. Initial glucose concentration was 104.3 mg per cent. ○, Control; ●, 0.1 per cent cetrимide; △, 0.25 per cent cetrимide; ■, 0.5 per cent cetrимide; ▲, 1.0 per cent cetrимide.

and proteins. For this reason the effect of pH on the uptake of glucose was investigated in some detail. In this set of experiments, glucose binding in the absence of the drugs was studied at pH 5.0, 6.0, 8.0 and 9.0. The results are shown in Fig. 1 and Table 2. The corresponding dose response curve showed a highly significant linear regression ( $P \ll 10^{-3}$ )—deviation from regression was only just equal to 0.05 and the equation for the curve is  $y = 93.27 - 2.89x$  (Table 3). Furthermore, the slope of the curve indicates much greater glucose uptake at higher pH. It is significant that the corresponding glucose control readings in twenty-eight experiments with which the homogenate glucose values have to be compared was  $104.35 \pm 0.64$  mg per cent. The differences between this value and those of the mucosal homogenate values at all pH levels was clearly significant. Parallel sets of experiments were carried out with 0.1, 0.25, 0.5 and 1.0 per cent cetrимide. The results are shown in Fig. 1 and Table 2, while a skeleton analysis of variance appears in Table 3. There is a continuous change in the slope of the dose-response curve from the lowest to the highest concentration. The difference in slope from that of the control is highly significant ( $P < 10^{-5}$ ) for the 0.5 per cent and 1.0 per cent but not significant for the two lower concentrations.

Table 2. MEAN GLUCOSE CONTENT OF HOMOGENATE WITH DIFFERENT CONCENTRATIONS OF CETRIMIDE AND AT DIFFERENT pH VALUES

Cetrимide (%)	pH 5	pH 6	pH 8	pH 9
0.1	81.88	74.84	70.08	64.8
0.25	79.00	78.90	75.81	71.80
0.5	84.37	85.17	84.37	82.93
1.0	84.97	83.71	85.13	84.65
0 (control)	79.28	75.16	72.40	65.92

After this work was concluded a number of auxiliary experiments were carried out to exclude ambiguities in the interpretation of results. In order to find whether the glucose was thrown down with the precipitate of protein, two tests were carried out in which the glucose estimation was performed on the whole homogenate without spinning. The means of four values at pH 5, 6, 8, 9 were 79.5, 72.0, 71.5 and 67.5 mg per cent respectively. Because this indicated that, contrary to the original concepts, the glucose was bound to soluble material in the

Table 1. GLUCOSE IN MG PER CENT ESTIMATED IN SUPERNATANT FLUID OF HOMOGENATE OF RAT INTESTINAL MUCOSA CONTAINING DIFFERENT CONCENTRATIONS OF DRUG

Mean reading of drug free controls was $75.18 \pm 3.9$ mg per cent		
	0.1%	1%
Cetrимide	80.13	87.22
Phloridzin	92.97	90.53
Sodium lauryl sulphate	78.73	86.59

homogenate, two experiments were carried out to test for uptake of glucose by the supernatant portion of the homogenate after spinning. The uptake was comparable since the reading gave a mean of about 73 mg per cent at pH 7.0. To exclude the possibility that the glucose was metabolized by surviving cells at room temperature, the glucose was estimated in a number of experiments immediately after addition. The readings obtained were 81, 74, 74, 71 mg per cent at the four pH values respectively, indicating that the bulk of the uptake occurred immediately. It was also found, in two experiments in which the glucose was estimated by the cyanide method<sup>7</sup>, that the readings did not differ from those of the control at any of the four pH levels. It became clear that the glucose which was present in the supernatant material all the time was split off by the more drastic cyanide method of estimation. In other words, the glucose-oxidase method was gentle enough to leave the binding intact, but even with this method this may only be relative and it is possible that the actual binding may be greater than is apparent from this method of estimation. In either case the question of conversion of glucose to other metabolites by surviving enzymes as a significant factor has been satisfactorily excluded.

Table 3. ANALYSIS OF VARIANCE, DOSE-RESPONSE LINES AND DIFFERENCE BETWEEN SLOPES WITH FIDUCIAL LIMITS FOR VARYING CONCENTRATIONS OF CETRIMIDE

	Control 0%	0.1%	Cetrimide 0.25%	0.5%	1.0%
Analysis of variance					
Source of variation					
Linear regression	$P \leq 0.001$	$P \leq 0.001$	$P < 0.005$	$P > 0.2$	$P \approx 0.2$

Dose response line					
$x = \text{pH}$	$y = 93.27$	$y = 98.18$	$y = 90.41$	$y = 87.1$	$y = 85.97$
	$-2.9x$	$-3.8x$	$-2.1x$	$-0.38x$	$+0.125x$
Differences of slopes from control		$P > 0.2$	$P > 0.2$	$P < 0.001$	$P \leq 0.001$

To determine whether the extent of the binding was constant, experiments were carried out to measure the unbound glucose remaining after standing with homogenate for different periods of time. The homogenate, diluted as already mentioned, was mixed with glucose to give a final concentration of 100 mg per cent, and analysed after varying time intervals. The results of these experiments are shown in Fig. 2, and indicate that the binding

Fig. 2. Estimated concentration of glucose in the homogenate measured at intervals after the addition of the glucose.

reaction was complete after about 20 min. Indications had been given in previous work that the capacity for binding glucose increased with the length of time the homogenate had been stored after the death of the animal. After standing for varying intervals of time, mucosal homogenates were mixed with glucose. These samples were analysed after 1 h, to measure the total extent of binding. The results indicated that the extent of binding increased markedly at first, but became almost constant 3 h after the death of the animal. In all the previous experiments the mucosa had been tested approximately 5 h after death and the degree of binding possible was therefore considered to be constant at this point.

Further experiments indicated that the rate of this change was affected by temperature. Both the rate and extent of glucose binding were less when the homogenate was stored at 4° C than at room temperature, and conversely were greater when stored at 37° C. It was therefore necessary to ascertain whether or not glucose binding occurred in the homogenate at the time of death, or whether it resulted from denaturation of the constituents of the homogenate.

To facilitate rapid removal of the intestine, the rat was anaesthetized with pentobarbitone and the intestine washed out and cleared of fat before its death. It is known that pentobarbitone does not affect the binding or the analysis. The homogenate was then rapidly prepared and diluted, mixed with glucose and analysed after 3 min. The readings were repeated at intervals of 3 min. The results of nine such experiments are summarized in Fig. 3, which shows that within a few minutes of the death of the animal the homogenate is capable of binding glucose. The regression coefficient is  $0.197 \pm 0.035$ , giving the apparent intercept on the ordinate axis of  $90.78 \pm 0.70$ . The correlation-coefficient ( $r = 0.774$ ) indicates that  $P$  is less than  $10^{-3}$ . It therefore seems probable that glucose binding is an inherent property of the intestinal homogenate but that the capacity for binding increases after death.

Fig. 3. Estimated concentration of glucose in the homogenate during the first 0.5 h after the rapid preparation of the homogenate.

Preliminary experiments have been carried out using homogenates obtained from sheep and pig intestines collected from a slaughterhouse. The results were qualitatively the same as those obtained with the rat. Preliminary experiments also indicate that glucose binding is increased after dialysis of the homogenate against distilled water, but the extent to which this is due to removal of electrolytes or to storage or denaturation of the protein requires further investigation.

# Respiration and EEG Synchronization in the Frog

by

J. ALLAN HOBSON

Department of Psychiatry,  
Harvard Medical School,  
Boston, Massachusetts

The correlation between respiration and the rhythmic EEG waves seems to be a result of stimulation of the olfactory system by the inflow of air.

SINCE Adrian's original report of the induction of synchronous electroencephalograph (EEG) activity by olfactory stimulation in the hedgehog<sup>1</sup>, a similar phenomenon has been observed in other mammalian species<sup>2-5</sup>. In a series of acute experiments in the frog, Ottoson has made an analysis of the induced slow potential and rhythmic waves in the olfactory bulb and presented strong evidence that the latter is the result of postsynaptic discharge of secondary olfactory neurons in response to excitation of receptors in the olfactory mucosa<sup>6</sup>.

In the course of an investigation of EEG activity in relation to the behaviour of unanaesthetized, freely moving frogs, a striking correlation between EEG synchrony and respiratory rate was observed. It is the purpose of this paper to show that such synchrony is the result of olfactory stimulation by nasal air flow incidental to normal respiration and that it is responsible for much of the grossly visible variability of the surface EEG in the frog. Both EEG synchrony and respiratory rate are positively correlated with the amount of spontaneous and responsive movement of the frog, and so it is possible that they are both valid indices of "arousal" in this species.

Twelve bullfrogs (*Rana catesbeiana*) weighing between 100 and 200 g were investigated in two acute and ten chronic experiments. Bilateral section of the olfactory nerves was performed in two frogs by opening the canal in which they course from the nasal to the cranial cavity and cutting the nerves under direct vision. Brain stem section was accomplished in two frogs by enlarging the foramen magnum until the medulla, cerebellum, and optic tecta could be seen and the midbrain interrupted between the latter two structures. All chronic animals were implanted with electrodes and allowed to recover for 48 h before recording began. Acute experiments were performed under urethane, light ether or after high cervical spinal section and local anaesthesia with 2 per cent metacaine infiltration. Silver-silver chloride recording electrodes were placed on the olfactory bulb, cerebral hemisphere, and optic tectum under mineral oil and led to the electroencephalograph. Electrical stimulation of nervous tissue was effected through insulated stainless steel electrodes with a Grass SD-5 stimulator. Experimental stimulation of the olfactory mucosa consisted in both acute and chronic preparations of blowing puffs of room or odorized air from a tuberculin syringe through a polyethylene tube (inside diameter, 0.5 mm) inserted up to 3 mm within an external nare. Respiration was recorded as the movement artefact between alligator clip electrodes attached to the skin of the throat and flank.

Bilateral synchronization of the EEG followed each exchange of air across the nares. As shown in Fig. 1, the response followed the initiation of expiration by 0.25–0.50 sec, consisted of a more or less rhythmic fusiform train of waves, increasing in amplitude from 10 to 25  $\mu$ V, and decreasing in frequency from 12 to 8 cycles/sec early in the 2 sec of its duration. Background activity could be faster or slower but was always of lower amplitude and usually irregular or desynchronized. EEG activity

in general, and synchronous bursts in particular, were of greater amplitude between anterior and posterior than between left and right electrodes. In monopolar or bipolar left-right derivations, the activity was seen most prominently over the bulb and hemispheres, but was often also clearly present in the tectal leads; this relationship followed a trend in background activity from slow synchronized rhythms anteriorly to rapid and irregular ones posteriorly as has been previously reported<sup>7</sup>. The activity completely disappeared when the animal stopped breathing, as it did for long periods at rest, or when it submerged, and it could be prevented by blocking the nostrils mechanically with vaseline. On the other hand, when the respiratory rate was high, either spontaneously or in response to 5 per cent carbon dioxide, it became continuous.

Insufflation of room air, ether, propanol or butyrate, in varying concentrations and at varying rates, to either nostril produced a train of waves qualitatively similar to those following each spontaneous respiration (Fig. 2). The induced activity could be seen to interact with the spontaneous bursts on which it was superimposed but it had essentially the same form even if the background activity was flat when the animal was not breathing. The frequency was highest at the onset of a train and fell to a constant level as the amplitude peaked and began to wane. The amplitude and duration of the response were proportional to the strength and duration of air flow but no odour specificity could be demonstrated. Thus, rapid injection provoked a short high-frequency burst whereas prolonged injection was accompanied by a sustained low-frequency discharge. The waves were quite resistant to adaptation as indicated by their appearance constantly in the spontaneously breathing animal and their repeated evocation by artificial stimulation. Failure to obtain a response, or unsystematic variations in responsiveness, seemed to be related to movement of the tip of the tube within the nasal cavity where only the central area of the mucosa is excitable<sup>8</sup>. When the tube was pushed through

Fig. 1. Intensification of amplitude and frequency of rhythmic EEG activity after expiration. The EEG is recorded from both left and right antero-posterior derivations (middle two channels). Expiration, beginning at arrows, is reflected in a burst of fast potentials in the EMG (top channel) and by a brief deflexion in the pneumograph (bottom channel) caused by flank contraction which is followed by increased amplitude of the slow, regular oscillations that are a measure of inspiratory throat movements. Calibration 25  $\mu$ V, 1 sec.

the internal nare into the mouth there was no response, which showed that expansion of the nasopharynx and lungs *per se* was not an effective stimulus. Similarly, artificial external contraction of the abdominal wall did not induce rhythmic waves. Continuous and intermittent visual, auditory and cutaneous stimulation neither produced nor blocked the response. Thus passage of air across the olfactory mucosa would seem to be the necessary and sufficient ingredient of effective artificial and natural stimuli, and it is likely that the response depends on the same structures and mechanism in both cases. No odour specificity was apparent but tests were limited and not conclusive.

Bilateral olfactory deafferentation had no effects on respiration but completely eliminated spontaneously and artificially induced rhythmic EEG activity in chronic animals, which indicated that the response is absolutely dependent on a pathway between the mucosa and olfactory bulb in the first cranial nerves. As has been reported in the cat<sup>3</sup>, acute section of the brain stem and division of the forebrain between tectum and hemispheres and between hemispheres and bulb eliminated the activity behind the lesion but did not alter the response in the anterior structures. The response can be seen in the absence of neural connexions between the brain stem and forebrain, justifying the conclusion that it is not primarily dependent on centrifugal influences. Anaesthetic doses of 'Nembutal', ether and urethane usually eliminated respiration and always abolished the induced waves; the EEG was characterized by continuous low-voltage fast activity in these conditions. Local installation of 2 per cent metacaine and 1 per cent procaine to the nasal cavity suppressed but did not entirely eliminate the response. The medullary brain stem was stimulated with currents of 100–200 cycles/sec at 1–3 V at several points after preparation of the animal under light ether anaesthesia; the characteristic response was inhibition of respiration and desynchronization of the EEG. If the stimulation enhanced respiratory rate or amplitude, synchronous waves were seen. After section of the cord at C-1, EEG synchrony could no longer be produced by brain stem stimulation. At no time did stimulation of the brain stem *per se* provoke rhythmic EEG activity and it had no consistent effect on artificially induced rhythmicity.

Identity of the response seen in the chronic frog with that elicited in the olfactory bulb by Ottoson<sup>6</sup> using natural and electrical stimulation in acute animals can only be assumed, but the frequency, amplitude, waveform and certain stimulus-response relationships favour this assumption. Ottoson demonstrated that one component of the response, a slow potential, originated in the receptor and represented synaptic activity at the level of the bulb. This change was not seen in the experiments reported here, probably because of differences in recording technique. A second component, the rhythmic waves, was

sensitive to asphyxia and could be blocked by antidromic stimulation of secondary olfactory pathways suggesting that it originated in postsynaptic neuronal discharge. More direct evidence shows that the mitral cells of the bulb fire in synchrony with the induced waves in the rabbit<sup>8</sup>. Although the precise relationship between cellular events and the EEG is not yet known, it is generally assumed that EEG synchrony is a reflexion of simultaneous electrical changes in many neurons. In the frog it is possible that such synchrony is established by the excitation or inhibition of many interconnected cells of the bulb and transmitted through parallel chains of neurons through axodendritic connexions in the surface of the brain. Such connexions have been known to exist since the work of Herrick<sup>9</sup>, who also predicted, on anatomical grounds, the predominant influences of olfactory input on the activity of the hemispheres in amphibia.

Rhythmic waves have now been reported to arise in response to olfactory stimulation in the brains of humans<sup>5</sup>, monkeys<sup>4</sup>, dogs<sup>4</sup>, cats<sup>3</sup>, rabbits, and hedgehogs<sup>1</sup> among the mammals, and frogs<sup>6</sup> and toads<sup>10</sup> among the amphibia. No reports have been found of such activity in the intervening reptilian and avian classes. In an early investigation they were sought but not found in fish<sup>11</sup>.

The response would seem to be physiologically homologous in all species. After latencies of 0.2–0.4 sec, rhythmic bursts of 15–40 cycles/sec with amplitudes up to 1 mV have been recorded in the bulb, pyriform and prepyriform cortices, the olfactory striae, amygdala, and hypothalamus in various animals. The intensity and duration of the response vary with the intensity and duration of stimulation. It is always eliminated by deep anaesthesia, and local anaesthesia of the olfactory mucosa usually eliminates the response, but isolation of the rhinencephalic structures from the rest of the brain does not alter the response. Stimulation of the reticular formation has been found to enhance the amplitude of the response but not to produce it in the absence of respiration.

There is thus reason to believe that the induced waves recorded in mammals and those reported here in the frog may share the same physiological mechanism. An important difference between the mammalian and amphibian response is, however, indicated by the wide distribution of the evoked activity in the frog. This difference is most likely a reflexion of the exclusively "olfactory" constitution of the amphibian forebrain which consists of bulb, pallial hippocampus, pyriform, and dorsal areas, and on the kinds of connexions within this primitive neuropil. There is no true cortex, not to mention neocortex, hence homologues of the mammalian cerebral areas which show this response are all that exist in the forebrain of the frog. An important consequence of this difference is the correlation of EEG synchrony in the frog with behavioural states such as movement or "arousal" in which respiratory rates are high; by contrast, resting states of the animal are associated with a low-voltage, fast EEG<sup>12</sup>. This is an opposite relationship to that which holds between the neocortical EEG and mammalian behaviour.

I thank Dr. E. Henneman for advice and James Spelios for technical assistance. The work was supported by a grant from the U.S. Public Health Service.

Fig. 2. Train of synchronous waves induced by injection of air into the nasal cavity. The channels are as in Fig. 1 and the time of the stimulus is approximately indicated by the solid black line under the tracings. Note that the background activity is synchronous in relation to a one-to-one throat-to-flank pattern of respiration and can be seen to interact with the evoked response. Calibration 25  $\mu$ V, 1 sec.

# Senescence and the Fidelity of Protein Synthesis in *Drosophila*

by

B. J. HARRISON  
R. HOLLIDAY\*

Department of Genetics, John Innes Institute,  
Hertford

The possibility that ageing may be a consequence of the failure of cells to maintain accurate protein synthesis has prompted experiments in which the larvae of *Drosophila melanogaster* are treated with agents expected to induce errors in protein synthesis. Treatment of larvae with amino-acid analogues or with streptomycin does indeed decrease the life-span of adults.

ORGEL<sup>1</sup> has suggested that a failure to maintain accurate protein synthesis could cause cellular senescence. Although the genetic material provides the precise information required for the synthesis of proteins, it would be expected that occasional mistakes in the transcription and translation of this information would occur<sup>2</sup>. He argues that for the majority of enzymes the presence of a few defective molecules would result merely in a slight lowering of metabolic efficiency, but that this would not be so for that group of enzymes which are themselves necessary for transcription or translation (RNA-polymerase, aminoacyl-*t*-RNA synthetases and probably those involved in *t*-RNA synthesis). Here a defective molecule with a lowered specificity of action would cause further defective molecules to be produced. Orgel shows that although the initial frequency of errors in a cell may be low, in the absence of cell division and selection for the most rapidly growing cells there would be an exponential increase in the frequency of errors leading to an "error catastrophe" and the death of the cell. In differentiated organisms in which the rate of cell turnover is low, with increasing age it might be expected that more and more cells would be affected in this way. This could in the end lead to the death of the individual, although other causes of senescence may of course be operating at the same time.

Orgel points out that one way of testing the hypothesis would be to increase artificially the frequency of mistakes in protein synthesis by treating cells with a non-toxic amount of an amino-acid or RNA base analogue. A pulse treatment should initiate an incipient error catastrophe, the effects of which should be seen on the cell, or the organism, long after the analogue has been withdrawn. We have carried out this test with positive results with *Drosophila melanogaster*, which is particularly suitable for this type of experiment. The actively growing larvae will readily feed on supplements added to their medium. After metamorphosis into the adult there is little or no further cell division, apart from the germ cells, so there is no likelihood of selection of healthy cells to replace any dying from inaccurate protein synthesis. The life span of the adult fly is relatively short, and it is of course possible to use genetically homogeneous material. Amino-acid analogues were used rather than base analogues, because the latter could possibly get incorporated into DNA and cause somatic mutations. An effect on longevity by base analogue treatments could therefore be attributed to this, rather than to an effect on proteins; whereas it is scarcely likely that mutations could be induced by amino-acid analogues. We should point out that there is no direct evidence that amino-acid analogues do get incorporated into proteins in *Drosophila*, but from the results with other animal cells or micro-organisms it would be expected that they would do so<sup>3</sup>. Amino-acid analogues could lower the

specificity of enzymes simply by getting incorporated in place of the natural amino-acid, or alternatively, they could get incorporated into the position normally occupied by some other amino-acid, if the appropriate activating enzyme for that amino-acid sometimes used the analogue as substrate. We have also used streptomycin, because there is now good evidence that by acting on the ribosomes this substance can induce mistakes in protein synthesis in both resistant and sensitive cells of *Escherichia coli* as well as in the *in vitro* protein synthesizing system<sup>4</sup>. It has not been possible to obtain comparable results with the *in vitro* system from mammalian cells (Williamson, A., personal communication), although there is a report that streptomycin may induce misreading in the synthesis of antibodies<sup>5</sup>.

In the first experiments, *F*<sub>1</sub> larvae from a cross between Oregon (v), that is with vermilion eye marker, and a black body, purple eye stock both inbred for more than 125 generations were used. In later experiments the parental line Oregon (v) inbred was used. The mated females were allowed to lay for 24 h on standard molasses/oatmeal medium, so the larvae were only partly synchronized. Third instar larvae were used in all the experiments; they were washed and then transferred to small Petri dishes containing a semi-synthetic medium essentially similar to the one developed by Prof. J. Crow, University of Wisconsin (5.4 per cent sucrose; 3.2 per cent dried yeast; 0.2 per cent 'Nipagin M' (methyl-*p*-hydroxybenzoate); 0.75 per cent agar) and either supplemented with analogues or streptomycin, or unsupplemented. Usually about 200 larvae were used for each treatment. The treatment was terminated by removing the larvae to tubes containing the same unsupplemented medium for pupation. When the pupae emerged the sexes were separated, and the males were kept in batches of ten flies in containers consisting of a 3 in. × 1 in. specimen tube containing about 5 ml. of a yeast extract, peptone medium (1 per cent yeast extract; 2 per cent bacto-peptone; 5 per cent sucrose; 0.2 per cent 'Nipagin M'; 1.5 per cent agar) which was attached by a short piece of 1 in. rubber tubing to a 4 in. length of 1 in. glass tubing plugged at the end with cotton wool. (This arrangement made it possible to provide fresh medium and remove dead flies without etherizing or manipulating the flies.) The tubes were incubated in the dark at 27° C and the flies were scored daily. Females were not used because there is good reason to believe that they are less good material for this kind of experiment than males. It has been shown that treatments which interfere with or prevent egg production (as might any effect on protein synthesis) have the effect of increasing the life span in *Drosophila*<sup>6</sup>.

Five amino-acid analogues were used. These were (natural amino-acid in brackets): canavanine (arginine), ethionine (methionine), *p*-fluorophenylalanine and β-2-

\* Present address: National Institute for Medical Research, Mill Hill, London.

thienylalanine (phenylalanine) and 4-methyl tryptophan (tryptophan). The first four of these are known to become incorporated into the protein of micro-organisms or animal cells<sup>3</sup>. In initial treatments it was found that none of the analogues had an effect on normal larval development at concentrations of  $10^{-3}$  moles/l. and only canavanine was noticeably toxic at  $10^{-2}$  moles/l. In all the longevity experiments the analogues were included in the medium each at a concentration of  $10^{-3}$  or  $2 \times 10^{-3}$  moles/l. (or twice these values for DL mixtures); either all the analogues were used, or 4-methyl tryptophan was omitted. The higher concentration of analogues did in fact have the effect of slowing down development in the longer treatment, but there was no detectable effect on larval feeding, pupation or on the phenotype of the adults. The streptomycin was included in the medium at a concentration of 1 mg/ml. Even a level five times higher than this had no effect on the larvae.

In the untreated populations a survival curve characteristic of a population showing senescence was always obtained. The curve consists of a long shoulder with very few deaths followed by a steep fall in the number of viable flies. As expected, the longevity of the  $F_1$  was greater than that of the inbred line, although the shape of the curve was much the same. It would appear that the conditions used allow a normal life span followed by senescence. In several experiments, treatment with either concentration of analogues was for 4, 8 or 24 h, using either  $F_1$  or inbred larvae. The general shape of the survival curve was similar to the control, but there were usually more early scattered deaths and the steep part of the curve was some days earlier than in the control. (The presence or absence of 4-methyl tryptophan made no difference to the result; as yet, however, we have no information concerning the separate or combined activity of the other four analogues). The survival curves for two of the experiments are given in Fig. 1. On the basis of the  $t$  test, the mean life spans of the treated populations in these experiments, as well as those in the other figures, are significantly lower than the controls ( $P < 0.02$ ).

Fig. 1. *a*, Third instar  $F_1$  larvae (*b pr* inbred  $\times$  Oregon (*v*) inbred) treated for 4, 8 and 24 h with ethionine, *p*-fluorophenylalanine, canavanine,  $\beta$ -2-thienylalanine and 4-methyl tryptophan, each at  $10^{-3}$  moles/l. —, Control (38 flies); — — —, 4 h treatment (54 flies); . . . . . 8 h treatment (64 flies); + + + +, 24 h treatment (56 flies). *b*, Third instar Oregon (*v*) inbred larvae treated for 8 and 24 h with ethionine, *p*-fluorophenylalanine, canavanine and  $\beta$ -2-thienylalanine each at  $2 \times 10^{-3}$  moles/l. —, Control (123 flies); . . . . . 8 h treatment (82 flies); + + + +, 24 h treatment (66 flies).

Fig. 2. Late third instar  $F_1$  larvae (*b pr* inbred  $\times$  Oregon (*v*) inbred) treated for 8 and 24 h with ethionine, *p*-fluorophenylalanine, canavanine,  $\beta$ -2-thienylalanine and 4-methyl tryptophan, each at  $2 \times 10^{-3}$  moles/l. —, Control (145 flies); . . . . . 8 h treatment (107 flies); + + + +, 24 h treatment (112 flies).

In one experiment we obtained a rather different result. In this the larvae were very near to pupation when they were put in the analogue mixture, and in fact some of them pupated during the treatment. The survival curves are shown in Fig. 2. It is evident that the treated population consists of two fractions: one which dies off 2–3 days after quite normal emergence, and the other which is much the same as those in the other experiments. The fraction of flies which died off quickly is greater (70 per cent) for the 24 h analogue treatment than for the 8 h treatment (40 per cent). The experiment suggests that there is a period immediately before the larvae pupate when incorporation of analogues has a very drastic effect on survival after metamorphosis. The life span of the non-sensitive fraction is affected in the same way as in all the other experiments.

We have found that treatment of larvae with streptomycin also causes premature death in the adult, but the extent of this effect varied from experiment to experiment. In general the  $F_1$  stock was more affected than the inbred one. An experiment showing an extreme effect and one showing an effect similar to that in most of the analogue experiments is shown in Fig. 3. In one experiment with the inbred line there was no detectable reduction in longevity.

It was essential to eliminate one possible trivial explanation of our results. Because all the media and tubes were kept sterile, apart from the medium on which the larvae were reared, it is possible that the analogues and streptomycin effectively sterilized the gut and the outer surface of the larvae, while the control larvae might remain infected. If a particular micro-organism enhanced the vigour of the adults, perhaps by producing an essential growth factor in the gut, then the sterile flies from treated larvae might be at a disadvantage and die earlier. We tested this by including some genetically marked flies (white eye and yellow body), reared in the usual way, with the flies from larvae treated with analogues or streptomycin. In this situation the experimental flies would be re-infected from the marked ones. It was found that the presence of these marked and naturally infected flies had no effect on the life span which was still materially reduced in comparison with flies from untreated larvae.

The finding that agents which might be expected to increase the normal frequency of errors in protein synthesis have the effect of shortening the life span does not of course prove that Orgel's hypothesis is correct, but it does confirm one of its main predictions. Other explanations are possibly applicable to our results. Clarke and Maynard Smith<sup>7</sup> have presented evidence that protein molecules in *Drosophila subobscura* have a long half-life, and it could be that if amino-acid analogues are present in the protein of young flies a substantial amount might remain in old flies. Assuming that this protein is defective in function, then these flies would have lessened vigour

Fig. 3. *a*, Third instar *F<sub>1</sub>* larvae (*b pr* inbred × Oregon (*v*) inbred) treated for 24 h with 1 mg/ml. streptomycin sulphate. —, Control (108 flies); ·····, streptomycin treated (50 flies). *b*, Third instar Oregon (*v*) inbred larvae treated for 24 h with 1 mg/ml. streptomycin sulphate. —, Control (123 flies); ·····, streptomycin treated (107 flies).

and the normal ageing process might be accelerated. This could be easily tested by experiments with labelled analogues. Another possibility would be much more difficult to test. If death of the organism is due to a random accumulation of deaths in a given number of irreplaceable cells, and if the larval treatments were toxic enough to kill a proportion of these cells during metamorphosis or soon after, then the normal process of random death of the remaining cells would kill the animals pre-

maturely. The fact that streptomycin is active in accelerating senescence argues against both these possibilities. First, there is no evidence that streptomycin would be incorporated into biological molecules and it is therefore unlikely to persist in the adult for long periods. Second, streptomycin, unlike the analogues, seems to have no toxic effect on the whole larvae at very high concentration; it therefore seems unlikely that it would kill substantial numbers of cells at the much lower concentrations which were used in the longevity experiments. Another relevant point is the main finding of Clarke and Maynard Smith that the rate of turnover of protein in aged *Drosophila* was twice as high as in young adults, which result can be explained on the basis of Orgel's hypothesis. If some of the protein being synthesized in aged animals is defective, then it is quite likely that there would be control mechanisms which would compensate for the lowered enzyme activity by stimulating further synthesis, while much of the abnormal protein would be denatured and degraded.

In contrast to many other theories of ageing, Orgel's has the virtue that it clearly defines in biochemical terms a possible basis for cell senescence. For this reason it makes rather specific predictions which can be tested both at the biological and the chemical levels. So far, in preliminary experiments, the main biological prediction has been confirmed. As well as expanding the present investigations, it is now clearly necessary to test whether the biochemical basis of the induced senescence is also as predicted.

We thank Professor J. Maynard-Smith for valuable discussions on this subject.

## Metabolism of Ribonucleic Acid during the Oestrous Cycle

by

T. H. HAMILTON\*

C. C. WIDNELL

J. R. TATA

National Institute for Medical Research,  
London, N.W.7

Variations in nuclear synthesis of RNA and turnover of RNA to the cytoplasm, as well as variation of the concentrations of RNA and protein in uterine cells during dioestrus and oestrus, appear to reflect changes in the rate of ribosome formation during the oestrous cycle.

It has been generally accepted that the cyclical nature of biological changes in the mammalian female urogenital system reflects responses to the variations in ovarian hormone titres. These titres are small during dioestrus or the luteal phase of the ovary and large during oestrus or the follicular ovarian phase<sup>1,2</sup>. Since the classical work of Long and Evans<sup>3</sup>, which described the oestrous cycle of the rat, this animal has proved to be a very convenient experimental organism for correlating fluctuations in endocrine activity with the responses of the target tissues, especially the interaction between oestrogen and the uterus.

Although the precise regulatory systems involved in the responses of uterine cells to fluctuations in the con-

centration of oestrogenic hormone remain unknown, work from many laboratories has now shown that oestrogen acts through the genetically controlled protein synthesizing machinery of the uterus<sup>4-7</sup>. In investigating the sequences of events during the early period of action of oestrogen on the uterus of the ovariectomized rat, we found that the acceleration of the rate of rapidly labelled nuclear RNA synthesis *in vivo* was the first response of the tissue to the hormone<sup>8</sup>. This response was also noticeable longer after hormone administration by a stimulation of DNA-dependent RNA polymerase activity in isolated nuclei, if the incubation was performed in the presence of magnesium ions only. There was only a slight and still later effect of hormone on the polymerase activity if the nuclei were activated with manganese ions and ammonium sulphate. It is significant that the RNA product of the

\* Present address, Department of Zoology, the University of Texas, Austin, Texas.

polymerase assayed in the absence of the salt is of a ribosomal type, whereas it is more DNA-like in the presence of the salt<sup>9,10</sup>, and that most of the rapidly labelled nuclear RNA in the uterus, the synthesis of which is accelerated by oestrogen, is also predominantly ribosomal. The maximum acceleration of the rate of nuclear RNA synthesis *in vivo* was observed within 20 min of a single injection of oestrogen; this immediacy of effect prompted us to look at possible variations in nucleic acid metabolism of the uterus during the two most prominent phases of the oestrous cycle in the rat.

We wish to report our observations of changes in RNA metabolism that accompany those of size and activity of the uterus during dioestrus and oestrus in the normal rat. Our findings show that (a) the concentrations of DNA, RNA and protein in the whole tissue or its cytoplasmic fraction vary during the two phases; (b) there is no variation in the concentrations of nuclear RNA and protein; (c) the rates of nuclear RNA synthesis *in vivo* and the activity of RNA polymerase activated by magnesium ions in isolated nuclei were significantly greater at oestrus than at dioestrus; and (d) the activity of RNA polymerase assayed in the presence of manganese ions and ammonium sulphate remained constant during the two phases of the cycle.

Wistar rats weighing about 185 g and repeating their oestrous cycles at intervals of 4-8 days were used in all our work. The state of the oestrous cycle was determined routinely by microscopic examination of vaginal cell types<sup>11</sup>. Vaginal washes were collected, dried, fixed and stained with methylene blue and the proportion of vaginal epithelial cells of non-nucleated (squamous or cornified) and nucleated types and polymorphonuclear leucocytes was then determined. In this way, rats in dioestrus and oestrus, but not in pro-oestrus or metoestrus, states were selected. In some experiments, vaginal cell-type determinations were made twice daily for 1 week before selecting the animals, and in all experiments the uteri were divided into two groups according to their weight. As a rule, the larger uteri, that is, those weighing 500-800 mg, were obtained from rats in oestrus, and the smaller uteri of 95-190 mg from animals in dioestrus as determined by vaginal cell-type ratios. In all experiments, a final vaginal histological preparation was made at the time the animals were killed for removal of the uteri.

Nuclei were isolated from the uteri, within a few minutes of their removal, by a procedure described by us earlier<sup>8</sup>. According to this procedure, 30 per cent to 59 per cent of the DNA was recovered in the nuclear fraction. The rate of nuclear RNA synthesis *in vivo* was followed by measuring the incorporation of uridine labelled with tritium into nuclear RNA obtained at different time intervals after injection of the radioactive precursor<sup>8</sup>. The activity of DNA-dependent RNA polymerase was determined by measuring the incorporation of ATP labelled with carbon-14 into RNA during the incubation of nuclei with magnesium ions alone or with manganese ions and ammonium sulphate, as described elsewhere<sup>10</sup>. Chemical procedures for estimating DNA, RNA and protein have also been described previously<sup>8</sup>.

Fig. 1 shows schematically the very marked differences in the size of the uterus and in the vaginal cell types from animals in the oestrous or dioestrous phases of the cycle. These changes found in our animals agree well with the cyclical variations described in the rat by other workers<sup>1,11</sup>.

Accompanying the cyclical variations in uterine size and vaginal cell types were corresponding changes in total DNA, RNA and protein in each uterus, as shown in Fig. 2. Uterine concentrations of DNA during oestrus were 15 to 20 per cent higher than those in dioestrus, indicating an increase in uterine cell population during this phase of the oestrous cycle. The physiological significance of this variation in the number of uterine cells for the two phases of the uterine cycle here examined is unknown. RNA levels increased during oestrus from 100 per cent to 125 per

\* Each value is the result of analysis of uteri pooled from ten animals.

cent over the values obtained at the dioestrous state. That this rise is not entirely a result of increase in cell number, but rather an increase in cellular content of RNA, is demonstrated by RNA/DNA ratios in whole-tissue homogenates for dioestrus and oestrus (Table 1). The data of Fig. 2 and Table 1 also show that whereas total uterine RNA and protein/DNA at oestrus were respectively nearly double and triple that at dioestrus, the RNA and protein contents of nuclei from animals in the two states were essentially the same. The wet weight of the uterus varies even more than the content of the foregoing constituents, having increased during oestrus by 400 per cent to 500 per cent over the dioestrous state. At a qualitative level these findings parallel Drasher's investigation<sup>12</sup> of variation in nucleic acid content of mouse uteri during the oestrous cycle.

The rate of nuclear RNA synthesis *in vivo* during dioestrus and oestrus was estimated from the incorporation of tritiated uridine into RNA after short-term and long-term exposure of the animals to the radioisotope (Table 2). For a 10 min pulse period the uptake of radioactivity by the whole tissue was greater during oestrus than in dioestrus. The changes in the total amount of radioactivity recovered, however, were also accompanied by a change in the distribution of tritiated uridine between acid-soluble and acid-insoluble fractions. There was a

Fig. 1. Illustration of the dioestrous and oestrous phases of the oestrous cycle of the female rat. Uteri are shown with ovaries but without posterior portions of vaginas. Insets show types of vaginal epithelial cells histologically recognizable at the two stages of the oestrous cycle. At dioestrus, vaginal cell populations are of two types: relatively small, nucleated epithelial cells and polymorphonuclear leucocytes. At oestrus, the epithelial cells are larger and of a non-nuclear, squamous or cornified type, and the leucocytes are absent.

Fig. 2. Variations in the concentrations of DNA, RNA, and protein in the uterus at dioestrus and oestrus. Wet weights are based on blotted but unruptured uteri immediately after excising. Bars denote ranges for triplicate determination on organs pooled from ten animals. Black columns, DNA; cross-hatched columns, RNA; hatched columns, protein; and white columns, wet weight (mg).

drop in the fraction of acid-insoluble radioactivity at dioestrus and the differences between dioestrus and oestrous states in the total tissue uptake of radioactivity and the fraction of acid-soluble radioactivity became more marked with increasing time after administration of tritiated uridine. When RNA was extracted from the acid-insoluble material obtained at 10 min after labelling with tritiated uridine, nearly all of the acid-insoluble radioactivity was recovered as nuclear RNA, whereas labelling of cytoplasmic RNA was observed only with the longer isotope pulse periods of 2 and 4 h.

The specific activities of nuclear RNA at 10 min to 4 h after administration of tritiated uridine for uteri in both the dioestrus and oestrous states (Fig. 3) are compatible with a turnover of RNA from the nucleus to the cytoplasm. These values were higher in oestrus than dioestrus for all intervals of exposure to the isotope, the differences being most pronounced at the earliest intervals. These results are interesting in view of previous findings from investigations of the synthesis and accumulation of cytoplasmic RNA in the uterus<sup>13,14</sup>. A significant increase in newly labelled cytoplasmic ribosomes of the uterus of the ovariectomized rat was observed 4 h after administration of oestrogen, after an earlier stimulation of nuclear RNA synthesis.

When the activities of the two DNA-dependent RNA polymerase reactions in isolated nuclei were examined, only the activity of the magnesium ion-activated RNA polymerase reaction was enhanced during oestrus, being 60 per cent to 70 per cent greater than in the dioestrus condition (see Fig. 4A). No difference between dioestrus and oestrus could be discerned when the nuclei were incubated in the presence of manganese ions and 0.4 molar ammonium sulphate. That the variation in the activity of the magnesium ion-stimulated RNA poly-

merase reaction is specific<sup>15</sup> for the uterus can be judged from the absence of any variation in hepatic nuclear RNA polymerase reactions during dioestrus and oestrus (Fig. 4B). A similar tissue specificity was observed in RNA polymerase activity when the growth of the ovariectomized rat uterus was stimulated by the administration of exogenous oestrogen<sup>8</sup>. Whether other tissues of the rat urogenital system which respond to oestrogen also exhibit the differential variation in RNA synthesis remains to be determined.

Our results show that cyclical variation in uterine cell mass and population is most markedly obvious both in the high content of cytoplasmic RNA and protein and in the nuclear capacity to synthesize RNA at oestrus which then declines, to possibly the lowest levels of the cycle, at dioestrus. The association between the two phases of the oestrous cycle on one hand and the rate of nuclear RNA synthesis *in vivo* or *in vitro* and in cytoplasmic levels of RNA and protein on the other is the physiological counterpart of experimental variations in uterine activity controlled by ovariectomy and exogenous oestrogen. It is interesting to note that the RNA polymerase activity of nuclei from normal rat uteri assayed in the presence of manganese ions and ammonium sulphate shows no response to fluctuations in titres of endogenous oestrogen, whereas, as already noted, nuclei from uteri of

Table 2. UPTAKE OF TRITIATED-URIDINE AND ITS DISTRIBUTION BETWEEN CYTOPLASMIC RNA AND ACID-SOLUBLE FRACTION OF UTERI FROM RATS AT DIOESTRUS AND OESTRUS

Oestrous cycle stage	Time after tritiated uridine (min)	Uptake of tritiated uridine (c.p.m./mg uterus)	Acid-soluble fraction (percentage of total tritium)	Specific activity of cytoplasmic RNA (c.p.m./mg.)
Dioestrus	10	220	68	0
	120	335	79	300
	240	596	86	1,824

	240	890	72	4,212

Rats were killed at the different time intervals indicated after the intraperitoneal injection of 100  $\mu$ c. of tritiated uridine (1,000 mc./mmole). Uteri from three animals in dioestrus or oestrus were pooled and processed as described elsewhere<sup>8</sup>. Cytoplasmic RNA was obtained from the supernatant fraction left after the sedimentation of nuclei from tissue homogenates.

Fig. 3. Incorporation of tritiated uridine into nuclear RNA isolated from uteri of rats at dioestrus and oestrus. 100  $\mu$ c. of tritiated uridine was injected intraperitoneally at different times before killing. Uteri from three rats were pooled and nuclear RNA isolated as described elsewhere<sup>8</sup>.  $\circ$ , Oestrus;  $\bullet$ , dioestrus.

Fig. 4. Activities of the two DNA-dependent RNA polymerase reactions in nuclei isolated from the uterus (A) or the liver (B) of rats at dioestrus and oestrus. Nuclei were prepared from organs pooled from ten rats and the enzyme activities were quantitated from the incorporation of ATP labelled with carbon-14, according to methods described elsewhere<sup>10</sup>. Both the magnesium ion-activated and the manganese ion and ammonium sulphate-activated reactions were dependent on the presence of all four nucleoside triphosphates and inhibited by ribonuclease and actinomycin D. Bars denote variation ranges for three determinations for rat-uterus nuclei and two for rat-liver nuclei. Black columns, RNA polymerase activity assayed in the presence of magnesium ions; hatched columns, RNA polymerase activity assayed in the presence of manganese ions and 0.4 molar ammonium sulphate.

ovariectomized rats exhibit a slight but delayed response to administration of exogenous oestrogen when assayed for this polymerase reaction (ref. 8 and unpublished work of T. H. Hamilton, C. C. Widnell and J. R. Tata). The product of the RNA polymerase reaction activated by manganese ions and ammonium sulphate is a more DNA-like type of RNA and of that activated by magnesium ions at low ionic strength is of a ribosomal type<sup>8</sup>. Much of the rapidly labelled uterine RNA in oestrogen-stimulated or unstimulated organs<sup>3-7</sup>, in common with that of other mammalian tissue nuclei<sup>16</sup>, is also of the ribosomal type. It is, therefore, quite likely that the rate of ribosome formation may be the rate limiting step in the regulation of uterine size and growth. A similar effect on the rate of ribosome formation preceding an accelerated protein synthetic activity has been found to be a key feature of the action of other growth-promoting and developmental hormones in their target tissues<sup>17</sup>. A continuous generation of ribosomes or ribosomal precursors is thought to be essential for the transport of messenger RNA from the nucleus to the cytoplasm<sup>17-20</sup>, and it is quite possible that the variations in RNA metabolism we have observed largely reflect a modulation of this process of RNA transport in the uterus during cyclical fluctuations in titres of oestrogenic hormone.

This work was supported in part by the U.S. Public Health Service. We thank Mrs. H. Katz and Mr. A. Bell for technical assistance. One of us (T. H. H.) was a fellow of the John Simon Guggenheim Memorial Foundation (New York) during this investigation.

## Action of Drugs in the Central Nervous System

by  
GLEND A. M. LAYCOCK\*  
A. SHULMAN\*

Department of Physiology,  
University of Melbourne

Titration of a series of closely related  $\beta, \beta$ -dialkylglutarimide homologues with each other, and against a series of depressant drugs, provides evidence that stimulation and depression can be initiated at the same sites in the central nervous system.

THE mechanism by which a hypnotic drug produces sleep in the intact animal and an analeptic drug effects convulsions when given alone, or arousal from such sleep when given together with hypnotic has been the subject of much intense investigation. Many hypotheses have been proposed which attempt to explain these processes

\* Present address: Department of Pharmacology, University of Melbourne.

in terms of the physico-chemical properties of the drug and certain physiological or biochemical functions of the responsive neurones, but the basic mechanisms are still largely unknown<sup>1,2</sup>.

On the basis of quantitative titration and structure-action investigations with  $\beta, \beta$ -disubstituted glutarimide and related drugs, it has been proposed that certain

hypnotic and analeptic drugs produce their opposed effects by a physical mechanism at common sites in the central nervous system (CNS) of mice and higher animal species including man, and the action and interaction of these substances, and of related anticonvulsive and psychoactive drugs, have been described in terms of present day theories of drug action. Analeptics are thought to act as agonists, hypnotics as antagonists, and drugs which show dual stimulant and depressant central actions as partial agonists by affecting the liberation or action of a transmitter substance, or both, at excitatory synaptic sites which may form part of reticular neurones concerned in the maintenance of arousal (refs. 3-7 and our unpublished work). It would follow, then, that titration of CNS stimulant and depressant drugs which act at these common sites against a homologous series of  $\beta, \beta$ -disubstituted glutarimides which show agonist, partial agonist and antagonist action should give rise to a series of titration curves of predictable form. This was confirmed in titrating pentobarbitone sodium against each of four homologous glutarimides with agonist (methyl, ethyl), partial agonist (methyl, *n*-propyl), or antagonist (methyl, *n*-butyl; methyl, *n*-amyl) action<sup>6</sup>.

This article describes the titration of the same series of homologous glutarimides against two further depressant drugs, hydroxydione (21-hydroxypregnane-3,20-dione sodium succinate), which is a sterol of high hypnotic potency and structurally unrelated to pentobarbitone sodium, and trimethadione (3,3,5-trimethyl-2,4-diketo-oxazolidine), which has very low hypnotic potency and is only remotely related to this barbiturate in structure and provides further evidence that these two hypnotics also act at the same common central sites<sup>3</sup>. The glutarimide homologues have also been titrated against each other, for it is considered that a close similarity between the forms of the titration curves for this series of homologous drugs, which almost certainly act at common sites, and those of the other drugs described here would provide support for the thesis that all these drugs act and interact at the same sites which are capable of mediating the opposed effects of stimulation and depression.

The titration procedure has been described before<sup>6</sup>. All drugs were injected intraperitoneally in aqueous solution with the exception of the *n*-butyl and *n*-amyl glutarimides, which were administered as a 1 per cent tragacanth suspension. Loss of righting reflex or clonic convulsions in 50 per cent of a group of mice was the titration end-point. The titration curves and regression lines representing the stimulant, depressant or dual stimulant-depressant action of the foregoing glutarimides against each other and against hydroxydione and trimethadione are shown in Figs. 1-3 and Table 1. Regression lines

Fig. 1. Titration curves and least squares regression lines (solid lines) representing titration of  $\beta$ -methyl- $\beta$ -ethylglutarimide against  $\beta$ -methyl- $\beta$ -n-butylglutarimide ( $\Delta$ ) and  $\beta$ -methyl- $\beta$ -n-amylglutarimide ( $\square$ );  $\beta$ -methyl- $\beta$ -n-propylglutarimide against  $\beta$ -methyl- $\beta$ -n-amylglutarimide ( $\blacktriangle$ );  $\beta$ -methyl- $\beta$ -n-butylglutarimide against  $\beta$ -methyl- $\beta$ -n-amylglutarimide ( $\bullet$ );  $\beta$ -methyl- $\beta$ -n-butylglutarimide against  $\beta$ -methyl- $\beta$ -n-amylglutarimide ( $\circ$ ). The titration end-point is hypnosis (or clonic convulsions in the case of  $\beta$ -methyl- $\beta$ -n-propylglutarimide against  $\beta$ -methyl- $\beta$ -ethylglutarimide) in 50 per cent of a group of mice. Each titration point is the mean of at least two concordant estimations.

representing titrations with pentobarbitone sodium<sup>6</sup> are also included in Table 1 for comparison. Relative stimulant and depressant potencies are shown in Table 2. The combined stimulant action of bemegride ( $\beta$ -methyl- $\beta$ -ethylglutarimide) and its *n*-propyl homologue and the combined depressant action of each hypnotic pair shown in Table 1 are represented by regression lines (of statistically significant difference,  $P < 0.001$ ). Further, as in titrations against pentobarbitone sodium<sup>6</sup>, the curves representing titration of the agonist  $\beta$ -methyl- $\beta$ -ethylglutarimide or partial agonist  $\beta$ -methyl- $\beta$ -n-propylglutarimide by their *n*-butyl or *n*-amyl homologues or by hydroxydione or trimethadione have the form of hyperbolae, but approximate relative stimulant and depressant potencies have been calculated where possible by fitting the titration points in each case by two least squares regression lines ( $P < 0.001$ ) which intersect and are probably different in slope ( $P < 0.001$ ). For each bemegride curve, the lower regression lines were calculated using all titration points which gave a regression line and an intercept with the *y* axis which showed least deviation from the (0,  $HD_{50}$ ) titration point (not more than 1.7

$P < 0.001$  in all cases. The titration end-point is hypnosis (or clonic convulsions in the case of MPG/MEG) in 50 per cent of a group of mice.

\* See ref. No. 6.

† Because of the curvature, a realistic regression line for the higher dose range was not calculable.

standard deviations). The intercepts of the positive slope regression lines of  $\beta$ -methyl- $\beta$ -*n*-propylglutarimide were all within 2.58 standard deviations from (0,  $HD_{50}$ ).

Fig. 2. Titration curves and least squares regression lines representing titration of  $\beta$ -methyl- $\beta$ -ethylglutarimide ( $\square$ ),  $\beta$ -methyl- $\beta$ -*n*-propylglutarimide ( $\circ$ ) and  $\beta$ -methyl- $\beta$ -*n*-butylglutarimide ( $\Delta$ ) by hydroxydione. The titration end-point is hypnosis in 50 per cent of a group of mice. Each titration point is the mean of at least two concordant estimations.

The form of the titration curves of bemegride against the hypnotics, glutarimide, hydroxydione or trimethadione, is similar to that against pentobarbitone sodium<sup>6</sup> (Figs. 1-3); further, the calculated anaesthetic dose at the point of intersection of each pair of lines is similar (Table 1). It has been suggested<sup>3,6</sup> that the deflexion of a hypnotic-anaesthetic titration curve marks the commencement of virtual saturation by the titrants of the common responsive sites and that the hypnotic has the higher affinity for the sites when the deflexion is towards the anaesthetic axis. It is concluded on this basis that bemegride has a lower affinity than its hypnotic homologues, hydroxydione or trimethadione. The similarity of the anaesthetic doses in the region of deflexion of the various curves supports the suggestion that each hypnotic may be associated with about the same number of responsive sites in producing the  $HD_{50}$  end-point. Similar findings and conclusions can be drawn from the titration curves of the partial agonist  $\beta$ -methyl- $\beta$ -*n*-propylglutarimide with hydroxydione or trimethadione. It should be noted, however, that, although the form of the curves for the hypnotic glutarimides is the same as that of the pentobarbitone sodium curve, the dose of the *n*-propylglutarimide at the point of intersection is less for the pairs of lines representing titration with the glutarimide hypnotics than that for those representing titration with the other three hypnotics (Table 1). We do not know why this is so.

The continuity and reversal in the slope of all the partial agonist titration curves (Figs. 1-3) provides, especially in the case of the homologous hypnotic glutarimides, good evidence for the suggestion that stimulation and depression are opposed responses initiated at common sites on responsive central neurones.

The reversal in slope obtained in titrating the highest doses of bemegride by its *n*-butyl or *n*-amyl homologue or by trimethadione (Figs. 1 and 3) requires special comment. This decrease in hypnotic requirement in the presence of very large doses of agonist is clear-cut, the  $HD_{50}$  titration end-point precise and readily reproducible, and the recovery of righting reflex rapid and uncomplicated, suggesting that the same basic mechanism is still operating at the neuronal level although in a modified fashion. This phenomenon has been observed previously in titrating a variety of hypnotics by large doses of anaesthetics<sup>8</sup>. It should be noted that in all such titrations the safe and clear-cut phase of decreased hypnotic requirement was invariably followed, as the dose of anaesthetic was still further increased, by one in which the mice showed persistent signs of stimulation in association with loss of righting reflex, followed later by death by respiratory depression, apparently of stimulatory origin. The nature of this fall is at present unknown, but it suggests that bemegride is not a pure agonist tending to show, when present in high doses, depressant action similar to that of its partial agonist homologue.

Fig. 3. Titration curves and least squares regression lines (solid lines) representing titration of  $\beta$ -methyl- $\beta$ -ethylglutarimide ( $\square$ ),  $\beta$ -methyl- $\beta$ -*n*-propylglutarimide ( $\circ$ ) and  $\beta$ -methyl- $\beta$ -*n*-butylglutarimide ( $\Delta$ ) by trimethadione. The titration end-point is hypnosis in 50 per cent of a group of mice. Each titration point is the mean of at least two concordant estimations.

Examination of the appropriate regression lines (Table 1) shows that there is a close relationship between the ability of low doses of the partial agonist  $\beta$ -methyl- $\beta$ -*n*-propylglutarimide to enhance the convulsant action of the agonist bemegride and the ability of the antagonist  $\beta$ -methyl- $\beta$ -*n*-butylglutarimide to increase the depressant action of its *n*-amyl homologue. The addition of one methylene group to the  $\beta$ -ethyl side chain of bemegride or to the  $\beta$ -*n*-butyl

Relative potencies were calculated from lower stimulant or depressant regression lines shown in Table 1.

side chain of  $\beta$ -methyl- $\beta$ -*n*-butylglutarimide appears to decrease the stimulant potency of the former drug and increase the depressant potency of the latter by a factor of about two in each case. These results agree with those obtained for titration of the glutarimide homologues against pentobarbitone sodium, hydroxydione and trimethadione (Table 2) and with the ratio of the  $CD_{50}$  values of the two stimulant glutarimides (1.8) or of the  $HD_{50}$  values of the two depressant glutarimides (2.0) (ref. 6). The relative depressant potency of the *n*-amylglutarimide and its *n*-butyl homologue (1.6), calculated from the negative regression coefficients representing their titration by the *n*-propyl homologue, also agrees with the foregoing estimates. The *n*-amyl and *n*-butyl homologues, however, are about equipotent in the positive slope region of the curves representing their titration by the *n*-propylglutarimide and also in the lower line region of the bemegride titration curves. Similarly, bemegride and the *n*-propylglutarimide seem to have about equal stimulant potency when titrated against both the *n*-butyl and *n*-amyl homologues. These exceptions may reflect in part the inadequacy of fitting regression lines to titration points which so obviously fall on a curve (Fig. 1); however, it seems more likely that other factors are important.

A comparison of the depressant activities of the hypnotics, from all relevant regression lines, shows that generally hydroxydione is twice as active as pentobarbitone sodium, which is in turn about 5–10 times more active than the glutarimide hypnotics and eighty times more active than trimethadione (Table 2). A similar two-fold difference in the depressant activities of hydroxydione and pentobarbitone sodium has been found in titrating these hypnotics against the anaesthetics,  $\beta$ -spirocyclopentaneglutarimide, pentylenetetrazol, diethadione and picrotoxin, again using the  $HD_{50}$  response of a group of mice as the end-point (our unpublished work).

With the exception of  $\beta$ -methyl- $\beta$ -*n*-amylglutarimide, the agreement in the magnitudes of the relative depressant activities of this series of glutarimide and non-glutarimide hypnotics, when calculated from the lower regression lines which represent the stimulant action of the partial agonist  $\beta$ -methyl- $\beta$ -*n*-propylglutarimide or the negative slope regression lines representing its depressant action, provides support for the view that this series of drugs acts and interacts at the same central sites. This evidence is convincing when it is observed that the relative depressant activities of this series of hypnotics, calculated in this manner, are so similar to those calculated from the regression lines representing their titration by the agonist bemegride or antagonist  $\beta$ -methyl- $\beta$ -*n*-butylglutarimide, homologues to which the partial agonist  $\beta$ -methyl- $\beta$ -*n*-propylglutarimide is intermediate both in structure and pharmacological action (Table 2).

The regression lines which represent the combined depressant action of  $\beta$ -methyl- $\beta$ -*n*-propylglutarimide and the hypnotics pentobarbitone sodium, hydroxydione,  $\beta$ -methyl- $\beta$ -*n*-amylglutarimide and trimethadione are parallel to those which represent combined depressant action of  $\beta$ -methyl- $\beta$ -*n*-butylglutarimide and each of these hypnotics (Table 1, Figs. 1–3); in other words, an equivalent increment of the *n*-propyl- and *n*-butylglutarimides in these circumstances produces an equivalent increase in depression. In terms of "rate theory" of drug action<sup>9</sup>, the parallelism suggests that the differences which exist between the rate constants of association ( $k_1$ ) and dissociation ( $k_2$ ) of the drug-site complexes and the relative penetrabilities to the responsive sites of these adjacent homologues are such that when the *n*-propylglutarimide, with the larger  $k_2$ , interacts in the presence of a limiting number of responsive sites, its depressant potency is equivalent to that of the *n*-butylglutarimide, which has a lower  $k_2$  and produces depression in conditions of freely available responsive sites. In producing equivalent depression, the *n*-propylglutarimide must involve a much

larger number of responsive sites than its *n*-butyl homologue because the  $k_2$  of the *n*-propylglutarimide is higher and a dosage of approximately 1,000  $\mu$ moles/kg is required to overcome its own stimulant action before depression, which shows as potentiation of hypnosis, is observed.

This quantitative investigation of the pharmacological interactions of pairs of closely related  $\beta$ , $\beta$ -dialkylglutarimide homologues with each other or with a series of structurally related or unrelated depressant drugs provides good evidence for the idea that the stimulant, depressant or dual stimulant-depressant actions produced by these drugs in the CNS of the mouse all arise at common sites.

Evidence has been presented here and elsewhere<sup>3,23</sup> from titrations using a large variety of CNS stimulant or depressant drugs with similar or widely divergent structures that the responsive sites lack specificity in the structural and polar requirements of drugs to which they will respond and it is now probable that the effects of a large variety of drugs which show predominantly stimulant or depressant action in low doses and the reverse type of action in high doses may all be mediated, although not exclusively, at these sites; the type of response produced is predominantly a reflection, in terms of "rate theory" of drug action<sup>9</sup>, of the relative drug concentrations presenting at the responsive sites and the relative magnitudes of the association and dissociation rate constants of the drug-site complexes<sup>3,6</sup>. Examples of drugs with dual stimulant and depressant action in the CNS have been reported widely among the glutarimides and related drugs<sup>3</sup>, volatile and local anaesthetics<sup>10–13</sup>, analgesics<sup>14,15</sup>, antihistaminics<sup>16,17</sup>, sterols<sup>18</sup>, and a variety of psychoactive drugs<sup>19,21</sup>. Titration of a number of such substances with the series of drugs described in this article are in progress and seem to support the proposition that such compounds show, in appropriate circumstances, the properties of partial agonists in the CNS; preliminary investigations relating to the apparently paradoxical actions<sup>1</sup> of 'Dilantin' and sodium 5-ethyl-5-(1,3-dimethylbutyl)barbiturate have been reported<sup>22</sup>.

We thank Mr. W. Kennedy and Mr. R. Silverstein for their assistance and Abbott Laboratories (Australia), Nicholas Pty., Ltd. (Australia) and the Pfizer Corporation (Australia) for trimethadione, the glutarimide drugs and hydroxydione ('Viadril') used in this investigation. This work was supported by the National Health and Medical Research Council of Australia.

## PLANETARY SCIENCE

## Cosmic Ice Residuum associated with an Astrobleme?

MANY circular to approximately polygonal structures on the Earth's surface have been described by geologists<sup>1</sup> as astroblemes—the result of impact between the Earth and extraterrestrial bodies—although not all geologists<sup>2</sup> accept this view of their origin. Some astroblemes have the form of craters and are associated with fragments of meteoritic iron. Others, more deeply dissected, are represented by a circular patch of sedimentary rock that originally filled the crater. Still others<sup>3</sup>, which include most astroblemes greater than 10 km in diameter, have a central uplift in which the strata are highly fractured and may be overturned. Surrounding this uplift is an annulus of impact breccia.

The ring structure at Gosses Bluff, a prominent topographic feature 150 km west of Alice Springs in the Northern Territory, Australia, has been described by the author<sup>4</sup> as an astrobleme. The ring structure exhibits the essential features of large astroblemes; the physiographic prominence of Gosses Bluff comprises the central uplift. The margins of the structurally disturbed area are obscured by younger surficial deposits, but outcrops of breccia and subsurface seismic and gravity data<sup>4</sup> suggest that the structure is about 14 km in diameter.

During a recent seismic survey<sup>5</sup> of the region in which Gosses Bluff is situated, gas was observed to blow from nineteen shallow seismic shot holes situated in the vicinity of the Bluff. Their distribution is indicated in Table 1.

Distance (km radius) from centre of Gosses Bluff	Total number of holes	Number of holes that blew gas
7	48	6
10	119	8
13	206	11
16	318	13
24	612	18

The more distant holes tend to cluster. Given the known occurrence of petroleum gas in the Alice Springs region, these shallow occurrences can be interpreted conventionally as pockets of petroleum gas, perhaps related to structurally controlled migration paths. An alternative explanation may, however, be tenable. The gas was detected only after a charge had been fired. The duration of the gas blows varied from a few seconds to more than 18 h. The stratigraphic unit in which the gas occurs, the Pertnjara Formation, was deposited under fluvial conditions and is "tight", having little porosity or permeability. The Pertnjara Formation is normal neither as a source rock nor as a reservoir rock for natural gas. The mode of release of the gas indicates that the gas is not trapped in interconnected pore space in the manner normal for natural gases. Were it normally entrapped, the gas would have blown from the seismic shot holes before the charge had been exploded, because the drill bit would have penetrated the interconnected system of pores. Fracturing of the rock by explosion is evidently necessary to release the gas, suggesting that it is located in non-connected pores and fractures. This is somewhat surprising in that the strata in the vicinity of the Bluff are known to be strongly fractured because of their involvement in the periphery of the central uplift.

One of the problems associated with astroblemes having a central uplift is the apparent absence of any meteoritic material associated with them. It does not appear sufficient to invoke normal processes of erosion to remove all traces

of meteoritic iron from such structures. Although their surface form is invariably considerably modified, debris from the impact is preserved in the annulus of breccia surrounding the central uplift. If a meteorite were to be disseminated explosively on impact, one might expect fragments of it to be incorporated in the impact breccia which is formed largely by comminution of the country rock. In fact, no examples of meteoritic material such as nickel-iron are known to me from breccias associated with astroblemes having a central uplift.

It is of interest therefore to consider the possibility that, in the case of Gosses Bluff, the bolide may have been a small comet with a nucleus composed of cosmic ice. Explosive dissemination of the nucleus on impact might be expected to result in the incorporation of some of the cosmic ice in the impact breccia and the forceful injection of some of the cosmic ice, or vapour derived therefrom, together with air under high pressure, into the shattered rock within and around the impact site. Entrapment would occur on the settling of material following the explosion. Such may be the origin of the near-surface natural gas encountered in the seismic shot holes in the vicinity of Gosses Bluff.

The possibility of such an origin for the gas may be checked first by determining the probability of impact between the Earth and a comet, and second, by comparing the composition of the gases encountered with those described from the tails and coma of comets.

Öpik<sup>6</sup> has estimated the likely frequency of collisions between the Earth and comets of various sizes. By taking the diameter of the Gosses Bluff astrobleme as 14 km, using the graph derived by Innes<sup>7</sup>, and assuming the impact velocity to be 20 km/sec, and the density of the comet as 1.3 g/cm<sup>3</sup> (ref. 8), the mass and the diameter of the comet can be calculated as 0.5 km. The Gosses Bluff astrobleme is believed to have formed during the Mesozoic<sup>1</sup> and for the purposes of this calculation the age will be taken as  $130 \times 10^6$  yr. During this span of time Öpik's figures suggest that 100 collisions between the Earth and comets of the size calculated may have taken place. The Australian land mass occupies about 1.5 per cent of the Earth's surface, and should therefore have received at least one 0.5 km diameter comet during the last  $130 \times 10^6$  yr. The Gosses Bluff astrobleme could thus well be the result of impact by a comet.

Wurm<sup>8</sup> lists the non-metallic neutral molecules identified within the heads of comets as CN, C<sub>2</sub>, C<sub>3</sub>, NH, OH, NH<sub>2</sub>, CH and O, and the ionized molecules identified in the gas tails and the region of the head as CO<sup>+</sup>, N<sub>2</sub><sup>+</sup>, CO<sub>2</sub><sup>+</sup>, CH<sup>+</sup> and possibly OH<sup>+</sup>. Whipple<sup>9</sup> considers that ammonia, water and CH<sub>4</sub>.6H<sub>2</sub>O may also be present in the heads of comets. No reliable quantitative estimates of cometary compositions are available.

Comparison of these data with those from the natural gases is difficult. Because encounter with gas in such shallow holes was unexpected, adequate sampling equipment was not available. Samples were collected by holding polythene bottles, which are permeable to hydrocarbons, over the blowing hole and also by displacement of water. Also the gases collected may have been contaminated by products of the explosions.

Seven gas chromatographic analyses of samples from separate holes have kindly been provided by Magellan Petroleum (NT) Pty. Ltd. A typical analysis of a sample from within 7 km of the Bluff gave hydrogen=2.8 per cent, oxygen=11.2 per cent, nitrogen=78.5 per cent, carbon monoxide=2.6 per cent, carbon dioxide=4.2 per cent, methane=0.7 per cent, helium—not detected (<50 p.p.m.); higher hydrocarbons—not detected (<20 p.p.m. methane equivalent). A sample collected 10 km from the Bluff 18 h after the gas flow commenced gave oxygen=16.7 per cent, nitrogen=74.2 per cent, carbon dioxide=6.7 per cent, water=1.5 per cent, methane=0.85 per cent, ethane=420 p.p.m., propane=20 p.p.m., butane—present (<2 p.p.m.), higher hydrocarbons and

hydrogen sulphide—not detected (<1 p.p.m.). The samples from holes remote from the Bluff are depleted in oxygen and nitrogen relative to carbon monoxide, and carbon dioxide; for example, hydrogen = 6.4 per cent, oxygen = 5.35 per cent, nitrogen = 46.8 per cent, carbon monoxide = 14.7 per cent, carbon dioxide = 22.2 per cent, methane = 4.45 per cent.

Air is apparently an important component of these natural gases. The elements present in combined form are also present in comets, sometimes in similar compounds. The occurrence of carbon monoxide in a natural gas is most unusual, and might suggest a cometary origin. The nitrogen compounds present in comets, however, are absent from the natural gas.

Without entire uncontaminated samples and some knowledge of the volumetric composition of cometary cosmic ice and the transformations that it might undergo during entrapment, further comparisons cannot be made. The similarities appear sufficient to warrant retention, for the present, of the theory that a significant part of the gas encountered is cosmogenically derived.

*Note added in proof.* Some other occurrences of shallow natural gas have recently been reported from the Alice Springs region in close association with concealed anticlines and faults in an area remote from Gosses Bluff. Analyses are not available.

## Surface Pressures in the Martian Highlands and Lowlands

CONFLICTING opinions have been expressed on the question of elevation of the Martian dark areas (maria) relative to the bright areas (deserts).

Wells, from his detailed survey of the Martian clouds<sup>1</sup>, has reported observations of stationary white clouds adjacent to (and presumably downwind from) the dark areas. Analysing this phenomenon, he expressed the opinion that the maria are elevated mountain ranges<sup>2</sup>. On the other hand, Miyamoto, mainly on the basis of his own observation of clouds at the Kwasan observatory correlated with observation by Dollfus, reached an opposite conclusion<sup>3</sup>: "the belt of deserts situated south of the maria belt and including Hellas and Argyre may be a highland belt" . . . and that "Dioscuria-Cydonia region may be a highland plateau or a mountain range". Thus Miyamoto supports the opinion of Tombaugh, that the deserts are elevated—an opinion largely based on a relative affinity for whitening and in part on radiometric measurements<sup>4</sup>.

Direct evidence concerning the relative elevation of the maria and the deserts has not been available<sup>5</sup>. Recently, measurements by more direct methods have been published, but the results do not yet appear conclusive.

As a result of analysis of *Mariner IV* data, Fjeldbo *et al.*<sup>6</sup> report that the immersion over desert Electris occurred at a highland relative to the emersion from occultation over Mare Acidalium. This result is based both on the pressure determination which is by about 70 per cent higher at emersion, and also on the occultation

radii measured from the Martian centre of mass. The radius at immersion (Electris) is calculated to be 3,384 km, and at emersion (Mare Acidalium) 3,380 km.

Sagan and Pollack<sup>7</sup>, on the other hand, point out that both at immersion and emersion the tangency point could lie in a bright area adjacent to a dark area. The measured pressures would in both cases be biased towards low values, if the two types of areas were characterized by differences in elevation.

From an analysis of radar returns at 12.5 cm, Sagan, Pollack and Goldstein<sup>8</sup> drew the conclusion that dark areas are elevated. They consider that the quasi-specular component, when displaced in longitude from a dark area, is more likely to originate on mountain slopes close to the subterrestrial point (which corresponds to the elevated maria hypothesis) than on the far slopes of depressions (which would be required if maria are depressions).

Sagan and Pollack<sup>7</sup> also mention the evidence of dust storms rising in the bright areas which, in some cases, were apparently deflected in their paths by major dark areas. Elevations on the Earth are cooler than the neighbouring lowlands, but an opposite situation could exist on Mars. The fact that maria temperatures reach a peak some 8° above the temperatures in the desert is explainable in terms of lower bolometric albedo<sup>9</sup>.

In view of the very recent spectroscopic determination of the Martian surface pressure<sup>9,10</sup>, if large altitude differences do exist, it is very likely that the surface pressures bracket the 6 mbar of the triple point of water, that is, pressure is higher than that in the lowlands and lower than in the highlands. Taking Tombaugh's figure of 20,000 ft. as a possible topographic difference<sup>4</sup>, and using a scale height of 9 km as determined by Kliore *et al.*<sup>11</sup> in the *Mariner IV* occultation experiment, a possible ratio of surface pressure in the lowlands to that in the highlands is obtained which is greater than two. Using a value of  $P_s$  of 8 mbar as determined by Spinrad *et al.*<sup>10</sup> for  $T_s = 200^\circ$  K as the median pressure, surface pressures can be visualized for the lowlands of  $P_L = 11$  mbar and for the highlands of  $P_H = 5$  mbar.

While the question of the diverging views of Wells and Sagan *et al.* on one hand and Miyamoto, Tombaugh, Fjeldbo *et al.* on the other is not yet definitely settled, the idea of the lowland maria with pressure greater by a factor of two than in the deserts offers an intriguing explanation within the framework of the "micro-hill" hypothesis for the Martian wave of darkening<sup>12</sup> of why the maria are subject to the seasonal darkening and the deserts are not.

The micro-hills are formed by the heaving action of moisture, when it freezes. Their creation is thus predicated on the absorption of moisture by the soil. This could conceivably occur at the lowest possible pressures mentioned for the Martian surface, below the pressure at the triple point of the  $H_2O$  phase diagram, by two separate mechanisms. One is the direct absorption by the soil of wind-carried water in the form of vapour. The second mechanism is the appearance of liquid water under an ice crystal, which is plausible in a small volume of a crevice not ventilated to the atmosphere. In other words, an ice crystal can be sublimating on top and melting from underneath. These two mechanisms, however, are not as likely to provide appreciable amounts of moisture to the soil as the mechanism of melting when ambient pressure is above the triple point of  $H_2O$ .

It is thus intriguing to attribute the association of the maria with the creation of micro-hills and the resulting darkening to the possible surface pressure difference of, say, 11 mbar in the maria as compared with 5 mbar in the deserts.

It should be made quite clear that standing water in the maria is quite unthinkable because the required water-vapour pressures cannot be maintained for any appreciable time. The  $H_2O$  liquid stage would be transitory even at 11 mbar, because the process of almost

instantaneous drying would be competing with the absorption by the soil.

If the absorption process does take up a large part of the vanishing ice crystal, the elimination of the whitening will progress more quickly in the maria than in the deserts—the specific heat of melting being much smaller than the heat of sublimation. The relative absence of whitening in the maria might thus be due not so much to the infrequency of depositions, but to the fact that they vanish more quickly. Especially if the ice crystals are formed in strong upward convection during the early afternoon and if deposition occurs on the still warm surface of the maria, the process of melting and vanishing can be quite fast.

The temporary invasion of the bright areas by the darkening process can be explained by the coincidence of  $H_2O$  deposition and a locally prevailing high pressure. According to circulation simulation by Loevy and Mintz (personal communication), variations in the surface pressure of the order of  $\pm 10$  per cent can occur. The temporary invasion by the darkening would thus be limited to regions of only the lowest deserts, that is, flatlands in the deserts which are only 1,000 or 2,000 ft. higher than the highest maria.

### Comparison of Relative Radionuclide Ratios in Debris from the Third and the Fifth Chinese Nuclear Test Explosions

Of the five first Chinese nuclear test explosions, No. 3 and No. 5 detonated on May 9, 1966, and December 28, 1966, respectively, have been the most powerful. According to the U.S. Atomic Energy Commission<sup>1</sup> both explosions were in the lower end of the intermediate range, that is, they corresponded to a few hundred kilotons of TNT.

Because a weapon in the intermediate range might be a thermonuclear device, special interest has been focused on the nuclear debris from these two tests.

Fig. 1. Air filter collected June 6, 1966, measured June 10, 1966.

Fig. 2. Air filter collected January 19, 1967, measured January 24, 1967.

Fig. 3. Smear test collected May 23, 1966, measured May 26, 1966.

Fig. 4. Smear test collected January 9, 1967, measured January 15, 1967.

Two sets of samples were collected after each of the two test explosions: airfilter (A) and smear tests (B). The airfilters were collected at ground level at Risø. Each sample consisted of a glass fibre filter (Whatman GFA) which weighed approximately 16 g, and which in 2–3 days had been passed by approximately 40,000 m<sup>3</sup> air. The smear tests were obtained by wiping the front parts of the DC-8 aircraft with pieces of cottoncloth when the aeroplanes arrived at Copenhagen. Thus there was a considerable difference between the two sampling methods, and a difference in sampling location, altitude and time after the explosion at which the debris was collected.

Four samples were used in the present study: two air samples A<sub>1</sub> and A<sub>2</sub> and two smear tests B<sub>1</sub> and B<sub>2</sub>. A<sub>1</sub> was collected on June 6, 1966, and A<sub>2</sub> on January 19, 1967, B<sub>1</sub> on May 19, 1966, and B<sub>2</sub> on January 9, 1967. These samples were selected because they showed the highest levels within each sample group.

The use of a lithium drifted germanium detector<sup>2,3</sup> connected to a 256 channel TMC analyser has made it possible to measure a number of  $\gamma$ -emitting radionuclides in several samples in a relatively short time without lengthy radiochemical analyses. Figs. 1–4 show some

examples of the spectra found in the samples. Only the photo-peaks used in the following were indicated at the figures.

The measurements of the *A* samples were all referred to 32 days after the date of explosion and the *B* samples to 14 days after. Table 1 shows the counting rates for the different nuclides in the photopeaks at these reference dates.

Table 1

Nuclide	Photo-peak keV	Half-life days	$A_1$ c.p.m.	$A_2$ c.p.m.	$B_1$ c.p.m.	$B_2$ c.p.m.
Zirconium-95	726	65	1.03	0.21	—	—
Molybdenum-99	144	2.79	—	—	1.37	6.32
Ruthenium-103	498	40	1.32	1.09	—	—
Iodine-131	364	8.05	0.90	0.70	—	—
Barium-140	162	12.8	1.22	1.62	0.105	1.91
Cerium-141	145	32.5	24.55	12.75	1.56	9.16
Cerium-144	134	284	5.87	0.92	7.31	0.47
Neodymium-147	91	11.1	7.52	2.01	0.77	3.50
Uranium-237	208	6.75	2.02	0.29	0.72	1.63
Neptunium-239	228	2.35	0.16	0.13	0.78	6.64

From replicate measurements the relative standard deviation of a single determination was determined at 10–15 per cent.

To compare the debris from the two tests cerium-141 was used as a reference nuclide, partly because it was rather abundant in all samples, and thus showed a small measuring error, and partly because this nuclide takes up a mean position as regards volatility<sup>4</sup>, that is, the 141-chain is neither very volatile nor very refractory. Table 2 shows the ratios between the cerium-141 nuclide ratios for the two types of samples.

Table 2 does not reveal any significant difference between samples *A* and *B* as regards ratios between the fresh debris from the May and the December tests. The table shows, however, that barium-140, and also probably neptunium-239, iodine-131 and ruthenium-103, were relatively more abundant, as compared with cerium-141, in the debris from the December test than in the May test debris. Zirconium-95 and uranium-237, on the other hand, were relatively more abundant in the May debris than in the debris from December. In all samples from the fifth Chinese explosion (compare Fig. 4) a prominent 81 keV peak was present. The half-life of the peak was determined at approximately 5 days and after an incineration of the sample at 600° C in 5 h the peak completely disappeared. Thus the peak was attributed to xenon-133 with a half-life at 5.3 days. This nuclide was not found in any of the samples from the May explosion.

It is concluded that the debris from the fifth Chinese explosion in comparison with the third was enriched in nuclides belonging to volatile decay chains (neptunium-239, ruthenium-103, iodine-131 and barium-140) as compared with the less volatile (molybdenum-99, neodymium-147 and zirconium-95). It is further evident that uranium-237 was relatively more abundant in the third than in the fifth Chinese test. While the first observation could be attributed to fractionation phenomena<sup>5</sup> it is not possible to explain the uranium-237 difference in this way because neptunium-239 and uranium-237 do not fractionate from each other, as the precursor of neptunium-239 is 23.5 min uranium-239. The explanation for the higher uranium-237 content in the May debris might be some additional production of uranium-237 by some other process than a (2n)-capture in uranium-235, perhaps by a (n,2n)-capture in uranium-238. The difference could, however, undoubtedly also be explained by differences in the weapon design (J. H. Harley, personal communica-

tion). The occurrence of xenon-133 in the smear test as well as in the air samples from the December explosion is another indication of the relative abundance of volatile nuclides in the debris from this test. How this noble gas is captured and contained in the two sample types is, however, still a subject of controversy.

### Search for Very High Frequency Radiation resulting from the Passage of Comet 1965f through the Solar Corona

ON October 21, 1965, a rare solar event occurred. The "Sun-grazing" Comet 1965f (Ikeya-Seki) passed through the solar corona at a perihelion distance of less than 500,000 km from the Sun's surface, or 1.66  $R_{\odot}$  from its centre, where  $R_{\odot}$  is the optical solar radius<sup>1</sup>. The rarity of such an event is shown by the fact that in the 23 yr from the discovery of radio emissions from the Sun in 1942 to the time of the present investigation, only two other known comets passed within 6  $R_{\odot}$  of the centre of the Sun. These were Comet du Toit (1945 VII), the perihelion distance of which on December 18, 1945, was 1.35  $R_{\odot}$ , and Comet Pereyra (1963 V), the perihelion distance of which on August 23, 1963, was 1.11  $R_{\odot}$  (ref. 2).

In view of this the Radio and Space Research Station's satellite telemetry reception equipment at Sembawang, Singapore (lat. 1° 25' N., long. 103° 49' E.), which operates at 136 Mc/s (2.2 m), was used to monitor solar radiation to find out whether or not the interaction of the comet with the region of the solar corona in which very high frequency radiation normally originates would produce any detectable increases. (The radio radius of the quiet Sun at 2.2 m is normally about 1.5  $R_{\odot}$ .)

The aerial system used consisted of a steerable array of eight Yagi aerials, which had a gain of 18 dB and with half-power beamwidths of 17° and 21° respectively in planes parallel and perpendicular to the individual elements. The output of the array was fed into a pre-amplifier at the base of the aerial tower and thence to a 136 Mc/s superheterodyne receiver. Because of the station's primary function as a satellite radio observatory it was not possible to obtain records of control data over long periods. The solar radiation was monitored continuously, however, from 02.50 to 04.40 U.T. on October 20 and from 03.05 to 04.20 U.T. on October 22. On the day on which the comet passed closest to the Sun (October 21) recording was carried out from 01.50 to 08.30 U.T., the time of perihelion being within about 2 min of 04.24 U.T.<sup>1</sup>. The comet was within 3  $R_{\odot}$  of the Sun for a period of about 1.5 h on either side of this time. Records were also made of the outputs of receivers tuned to 20 Mc/s and 40 Mc/s, connected to dipole aerials, in order to find the times when atmospherics or other local interfering noise were present.

Although a considerable number of atmospherics were recorded in these periods, on only one occasion was there any disturbance that could be attributed to the Sun. This was at 07 h 19 min 22 sec U.T. on October 21, when a 4 dB increase in signal level lasting 15 sec occurred (corresponding total peak flux density  $\approx 1.6 \times 10^{-21}$  W m<sup>-2</sup> (c/s)<sup>-1</sup>). By this time the comet had receded to a distance

Table 2

S.D.  $\sim$  30 per cent.

of  $4.7 R_0$ , and thus it seems unlikely that it could have resulted in the observed enhancement. We conclude that the interaction of the comet with the solar corona did not produce any significant enhancement of emission at 2.2 m wavelength.

This work was carried out as part of the programme of the Science Research Council Radio and Space Research Station. The observations were made by the staff of the Radio and Space Research Station at Singapore under the direction of A. Moorat and C. R. Carter. M. P. Candy, Director of the Comet Section of the British Astronomical Association, provided valuable information on cometary orbits.

### Amino-acids in Recent Sediments off South-east Devon, England

RECENT results<sup>1-3</sup> on the amino-acid content of marine sediments have related to basin deposits; the diagenetic alteration of these may not be strictly comparable with analogous changes in shelf sediments.

A sequence of drowned freshwater, intertidal and shallow water marine sediments from off the coast of south-east Devon has recently been described<sup>4</sup>; these sediments were largely deposited in association with the Flandrian (Post-glacial) transgression. The total, combined<sup>5</sup> amino-acid content of some of these sediments has been determined by a method described elsewhere<sup>5</sup>. Accuracy was generally better than  $\pm 20$  per cent; some amino-acids such as proline could not be quantitatively

determined when encountered, but errors were minimal from such losses.

Work was largely confined to two gravity cores that were collected from latitude  $50^{\circ} 30' 30''$  N., longitude  $3^{\circ} 25' W.$ , at a depth of 75 ft. (23 m) below O.D. Decca position fixes showed that the two sample localities were within 600 ft. (183 m) of each other. The principal compositional features of the cores are shown on Fig. 1, which also indicates the area studied.

Core 1 contains a thin peat bed near the base (Fig. 1) that has been dated by radiocarbon analysis at

$$8,580 \pm 830 \\ - 755 \text{ years B.P. (NPL-86)}$$

This date confirms the results of pollen analyses of sediments in core 1, which indicate a zone VI b age for the peat and the overlying intertidal sediments<sup>4</sup>. The muddy sand overlying the intertidal mud in cores 1 and 2 was probably deposited in the sub-littoral zone after the inundation of the contemporary coastal region by the transgressive shoreline; the rate of rise of sea level at this time was about 5 ft./century. Assuming a contemporary mean tidal range of 10 ft. (an approximate mean of the present-day tidal range off Teignmouth) and a depositional zone of  $-5$  to  $-25$  ft. below mean sea level, then deposition of the muddy sand was probably completed within 500 years of the establishment of marine conditions at any point. The suggestion is that the muddy sand in cores 1 and 2 may be assigned an age of 7,500 years B.P., with a probable error either way of not more than 500 years.

Fig. 2 indicates the amino-acid content of the muddy sand in cores 1 and 2, and also shows the results of simple humic acid extractions carried out on core 2 (humic acid was dissolved in 0.3 normal sodium hydroxide solution and then precipitated by adjusting the pH to 1). Semi-quantitative analyses of the intertidal mud and the peat bed in core 1 indicate that these sediments contain about 3,500 p.p.m. total amino-acids, the following being present in both deposits: phenylalanine, lysine, arginine,

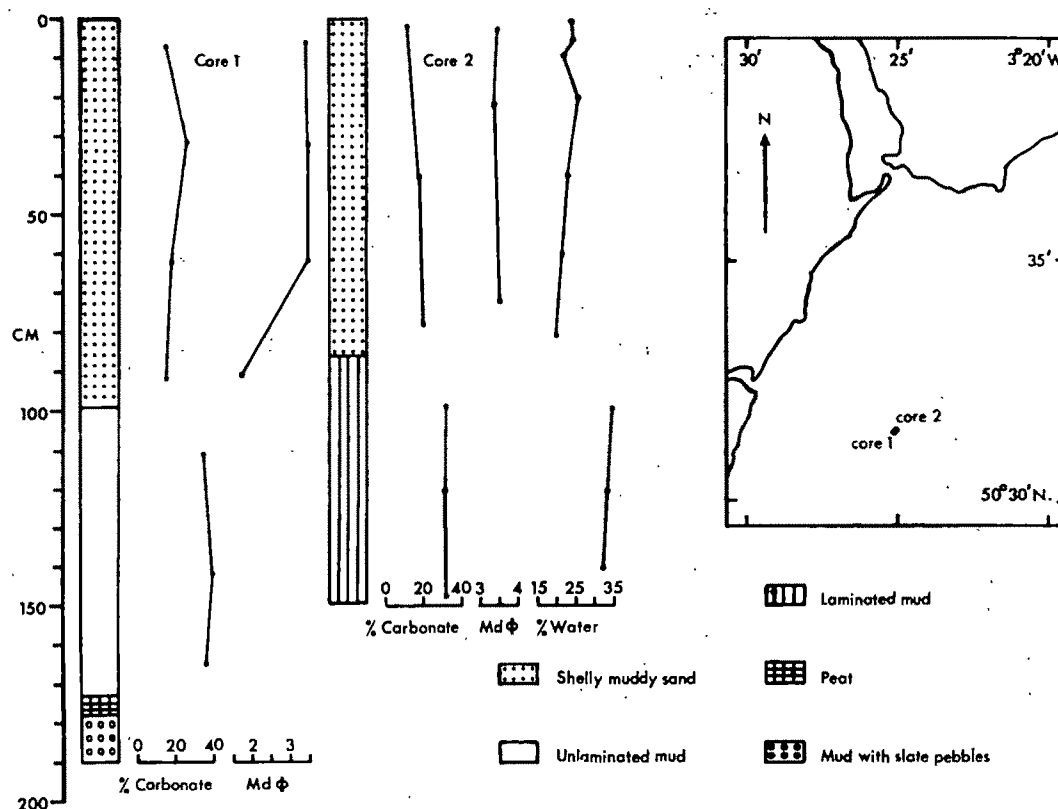

Fig. 1. Compositional characteristics of cores 1 and 2, together with a sketch map of the sampling locality. Water content of core 2 is expressed as a percentage of the wet weight of the sediment.  $Md\phi = \phi_{50}$  percentile where  $\phi = -\log$ , (diameter in mm).

glutamic and aspartic acids, glycine, serine, valine, alpha alanine, leucine, threonine and cysteine. Traces of proline were found in the mud sample (139–141 cm, core 1), and traces of tyrosine occur in the peat. All results are expressed as a proportion of the dry weight of the sediment.

Samples from core 2 were collected and analysed 1 week after the collection of the core; core 1 was analysed after storage in a darkroom for 6 months. Both cores were collected and stored in impervious fibreglass liner tubes which retained the interstitial water of the sediments. After a few weeks storage, microbial activity in the muddy sand led to the formation of black hydrotroilite in core 1. Black patches in some other muddy sand cores from the same area indicate that this reduction process is locally in operation on the sea-bed at present. Pyrite, evidently authigenic, fills some larger foraminiferal tests that are present in the mud and the muddy sand in cores 1 and 2. Pyrite formation in the muddy sand is largely confined to that part of the sea-bed that is underlain by considerable (more than 10 ft.) thicknesses of superficial sediment<sup>4</sup>, and is possibly associated with the expulsion of oxygen-depleted water from these (compacting) sediments. The lowermost increase in the abundance of amino-acids in the muddy sand in core 2 (Fig. 2) may also be associated with the expulsion of interstitial water (and amino-acids in solution) from the intertidal sediments beneath—this process has apparently been of negligible importance in core 1, where the intertidal sediments have a proven thickness of only 74 cm.

The amino-acid profiles for the two cores are similar (Fig. 2). The results for the top of core 2 may have been complicated somewhat by the presence of a *Turritella communis* Risso, and a sipunculid worm in the water-filled space above the core; these animals were alive and may have been feeding. The marked increase in the abundance of lysine in the upper few centimetres of both cores is possibly the result of microbial synthesis<sup>6</sup>. The

rapid fall-off of abundance with depth for both cores is probably not analogous to the superficially similar data for San Diego Trough sediments<sup>2</sup>, mainly because the muddy sand was deposited during a short period of time; depth in the muddy sand cannot be equated with age in the same way as it can in the San Diego Trough sediments.

Assuming a sub-littoral depositional environment for the muddy sand<sup>4</sup>, it might be expected that the net rate of deposition would be rapid initially and then decrease in proportion to the declining turbulence of the environment as the sea level rose and the shoreline migrated landwards. If another assumption can be accepted—that the supply of proteinaceous material (and humus) to the environment remained fairly constant during the deposition of the muddy sand—then it is clear that the amino-acid profiles can be explained on this basis. The apparent lack of humic acid below 10 cm in core 2 may also be a result of rapid deposition of the sand below this depth and a consequent dilution of the supply of humic material to values less than the detection limit of the extraction method (about 0.01 per cent).

If the amino-acid profiles in the muddy sand are a direct consequence of the mode of deposition, it is clear that diagenetic changes involving the organic constituents of the muddy sand have been slight since deposition ceased about 7,500 years ago. Mild reducing conditions, established within the sediments soon after deposition had ceased, probably assisted in the protection of the organic material (compare ref. 1).

The carbonate content of the muddy sand averages about 15 per cent (Fig. 1) and consists largely of whole or broken molluscan shells, together with a small contribution from microfungal tests. In order to test the hypothesis that the proteinaceous material in the muddy sand might be largely confined within the structure of the shell debris<sup>7</sup>, semi-quantitative analyses of some of this material were carried out.

Fig. 2. Individual amino-acid content of cores 1 and 2 (abbreviations as in ref. 2) expressed as p.p.m. of the dry weight of the sediment. Also shown are the total abundance of amino-acids in cores 1 and 2, and the humic acid content of core 2.

An analysis of *Turritella communis* shells from a muddy sand core from latitude  $50^{\circ} 27' 30''$  N., longitude  $3^{\circ} 25'$  W., depth 90 ft. (27 m), revealed the presence of traces of cysteine, proline and tyrosine, and about  $10 \pm 5$  p.p.m. of the following: phenylalanine, lysine, arginine, glutamic and aspartic acids, glycine, serine, valine, alpha alanine and leucine, giving a total content of amino-acids of about  $80 \pm 30$  p.p.m. The absence of threonine is notable; otherwise the assemblage is similar to that in the bulk sediment samples. The abundance of amino-acids in these shells is too low to make a significant contribution to the bulk content of the muddy sand.

A bulk sample of foraminiferal tests was taken from several samples of muddy sand with carbon tetrachloride flotation. Material soluble in acid weighed 1.62 g; insoluble parts such as pyrite and sand were removed before the acid hydrolysis. The foraminiferal tests contained about  $250 \pm 50$  p.p.m. total amino-acids, the range in abundance being about 20 to 60 p.p.m. The following compounds were identified: glutamic and aspartic acids, glycine, serine, valine, alpha alanine, leucine and threonine. The restricted nature of this assemblage, despite the presence of many species of foraminiferids, is of interest, but clearly the abundance of amino-acids in the foraminiferal tests can only account for a small fraction of the bulk content of the muddy sand.

Having eliminated the shelly material as a possible source of the amino-acid content of the muddy sand, there remains the probability that a large proportion of the amino-acids (or their polymers) are attached to clay minerals, and possibly humic compounds, within the finer fractions of the sediment<sup>2</sup>.

This work was carried out in the Department of Geology at the University of Bristol under the supervision of the late Professor Whittard, and with the support of a research studentship from the Department of Scientific and Industrial Research.

### Archaeomagnetic and Palaeomagnetic Study of the Magnetic Field of the Earth in the Past 600,000 Years

DIRECT observations provide information about the variation of the Earth's magnetic field only during the past 400 years, but these records can be considerably extended by archaeomagnetic and palaeomagnetic investigations. This article reports new information on variations of the Earth's magnetic field based on data gathered from three sources. These are (1) measurements of the thermoremanent magnetism of baked clay samples, which provide information about the past 6,800 years;

Fig. 1.

Fig. 2.

(2) measurement of magnetic declination and dip on loess samples from a defile of layers in South Moravia 18 m thick; (3) investigation of the magnetization of baked clays and porcelanites produced by the underground combustion of Tertiary coal deposits in North Bohemia which have acquired high thermoremanent magnetization during the Quaternary—that is, during the last 600,000 years.

Archaeological samples from Czechoslovakia<sup>1</sup> have been taken from baked clays, kilns and potteries for the interval from 4,400 B.C. up to the present time. The age of some has been determined archaeologically and the age of others by means of the carbon-14 method. Also, samples of baked clay (which date from 6,500 B.C. to 5,400 B.C.) from Catal Hüyük in Turkey have been measured in collaboration with A. A. Mellaart. Because the total Earth's magnetic field intensity was investigated by the double heating method it was possible to determine the ratio between the past and present Earth's magnetic field (coefficient  $k$ ), using heating and cooling curves of remanent magnetization<sup>2</sup>. The data from Turkey yield the coefficient  $k$  equal to 1.35 for the samples dated at 6,500 B.C.,  $k = 1.25$  for those at 6,000 B.C. and  $k = 1.15$  for those dated at 5,400 B.C. For the Neolithic samples from Czechoslovakia the values of  $k$  vary from 0.8 to 0.5 depending on the age in the time interval 4,400–3,500 B.C. During the Eneolit a gradual increase of the values  $k$  takes place which continues up to a maximum value of  $k = 1.5$  (400 B.C.). Then the field intensity decreases up to the present. It follows from the curve (Fig. 1) that the changes of the field have an almost periodical character; the length of the period amounts up to 3,500–4,000 yr and the amplitude changes from 0.5 (about 3,500 B.C.) to 1.5 (approximately zero) times the present field intensity.

Previously determined archaeomagnetic curves which represent the changes of the Earth's magnetic field intensity in the world are given in Fig. 2. The comparison shows good agreement among French (1) (ref. 2), Georgian (2-USSR)<sup>3</sup>, Japanese (3) (ref. 4) and Czechoslovak (4) curves. On this basis it would be possible to judge on the planetary character of the changes of the Earth's magnetic field. On the other hand the Indian curve (5) (ref. 5) exhibits a decrease of intensity going back in time; the

Fig. 3.

suppose that the direction of magnetization of individual layers represents the direction of the field that acted in the time of gradual accumulation of the layers. Besides brown coloured loess and fine grained orange sandstones layers of humus are also present and the magnetization of these is fairly high.

The values of  $D$  and  $I$  are plotted on a stereographic net (Fig. 3). The spiral character of the changes when we proceed from the oldest to the youngest samples is apparent. The spiral continues anti-clockwise, the declination changing in the range of  $-40^\circ$  to  $+53^\circ$  and the dip in the range of  $54^\circ$  to  $75^\circ$ . Naturally, this spiral cannot express quite fully the continuous changes of the Earth's field direction, but from its path (especially in the time interval 55,000–52,000 yr) it is possible to deduce that the changes in direction hardly exceeded the area bordered by the outside contour of the spiral. It is remarkable that the changes occur in the direction opposite to that supposed some years ago; the results concerning this anti-clockwise trend, however, agree with changes of the pole position that Japanese geophysicists have obtained for the period 600 to 1950 yr<sup>7</sup>. Our data may be supposed to characterize a longer temporal process (the secular variation is probably partially averaged in the samples). This means that the shorter temporal changes observed in the course of some hundreds of years at magnetic observatories would superpose the movement obtained by us on the loess. This also follows from the large diameter

Fig. 4.

maximum about zero A.D. is not apparent. It is possible, therefore, to make a conclusion that the character of the field seems to be similar at the same geographical latitudes, while near the equator the sharper influence of the westward drift changes the course of the curve somewhat.

The magnetic declination and dip of loess deposits up to 60,000 yr. old have been investigated. A profile 18 m thick at Věstonice (South Moravia)<sup>6</sup> represents a basis for a gradual temporal dating of the last glacial series because of the possibility of its detailed stratigraphical division. The main horizons have been dated by means of radiocarbon and the layering was investigated palaeontologically. The age for five suitable horizons was determined to be 55,000; 52,000; 28,100; 18,600; and 14,800 yrs respectively. Cubic samples were taken from the layers and the directions of their remanent magnetization were determined. After measuring the samples the declinations and dips were calculated. Taking into consideration the fact that the rocks are very fine grained, we may

b

Fig. 5.

of the spiral compared with the observatory data, for example for London.

The determination of the total Earth's magnetic field vector for approximately 25,000 yr B.C. from double heating measurements of ten samples from baked clays and archaeological kilns from Věstonice made it possible to obtain the coefficient  $k=0.5$  which means that the field then had 0.5 times the present day field intensity. The cooling and heating curves for one representative sample are given in Fig. 4.

During the Pleistocene underground fires broke out in the North Bohemian Tertiary coal basin, the cause of which was spontaneous oxidation processes within the coal layers. It resulted in baking the rock cover, especially clays, sandstones, gravels, which were changed into new types of rocks (porcelanites, palaeoslugs). Consequently, the rocks were mineralogically stabilized and thermoremanent magnetization, in most cases with a high stability, was produced. This enables us to use these rock samples for the examination not only of the direction but also the intensity of the Earth's magnetic field at the time of the fires. The progressive double heating method has been used for thirty samples of porcelanites and palaeoslugs from eleven localities.

These rocks can be classified into approximately three groups—the lower, middle and upper Pleistocene. The paths of two typical heating and cooling curves are given in Fig. 5(a) ( $k=0.31$ ) and 5(b) ( $k=1.5$ ). The values of the Earth's magnetic field intensity at the time of the heating of the clays in the different localities ranged from 0.31 to 1.5 times the present day field intensity (see Table 1). For the two oldest groups the age of which is supposed to be lower Pleistocene, we have found reversed remanent magnetization with, for the first group,  $k=1.2$  and for the second one  $k=0.96$ . The mean values of declination and dip for the groups measured are given in Fig. 6 and exhibit clustering not far from the present field direction; the older groups give a somewhat lower dip.

The aim of this investigation was to determine the behaviour of the Earth's magnetic field in time for an interval of some 100,000 yr. The results indicate that the total Earth's magnetic field intensity had a periodical

Fig. 7.

character, at least in the last 8,500 yr. This period was approximately 7,500 yr, and the amplitude was between 0.5 and 1.5 times the present day field intensity. In the older epochs (in the Pleistocene) the amplitudes of the Earth's field varied from 0.3 to 1.5 times the present day field intensity. The amplitudes of these intensity variations probably continued to increase going back in time and resulted in reversals of polarity (observed in the lower Pleistocene) at first for shorter time intervals. Later the periodical course of the field would pass to reversed polarity. The probable schematic course of the dynamic changes of the field intensity for the last 600,000 yr is given in Fig. 7. The intensity of the reversed field increased as our results show to approximately the same value as that of the present day field intensity.

Table 1.

Age	Locality	$k = F_p/F_0$	$F_0$ (present field = 0.475 Oe)	Mean value
Upper Pleistocene	D	1.44, 1.38	1.43 1.41	1.42
	N	1.38 1.29	1.30 1.28	1.31
Middle Pleistocene	Za	1.16	1.05	1.10
	Z	0.98	0.90	0.94
	Tg	0.83	0.83	0.83
	B	0.54	0.44	0.49
	Ho	0.31	0.41 0.50 0.46	0.42
Lower Pleistocene	K	1.15	1.20 1.28	1.21
	S	0.80	0.80	0.80
	C	0.58	0.72	0.66
	V	-1.06	-1.11 -1.35	-1.17
	V'	-0.97	-0.96	-0.96

As for the declination and dip, the changes of the Earth's magnetic field direction took place with substantially greater amplitudes some 10,000 yr ago, when the range of changes of declination were 70° and of dip, 25°.

## PHYSICS

### Retro-reflexion by Diffusing Surfaces

R. J. SEANEY<sup>1</sup> appears unaware of previous observations over some 30 years<sup>2-4</sup>.

The apparatus which I devised 2 years ago (Fig. 1) enables the retro-reflexion from diffusing surfaces to be seen easily and binocularly. A pseudo-image of the source is seen at X, more or less sharp, according as the retro-reflexion is confined to a small solid angle or not. A pointer previously erected at image-point X helps to

locate it in space. The light source should be as small and as bright as possible. A crisp spot is given by most white paper or card, smoked magnesium oxide, magnesium oxide powder between glass, silica powder between glass (irrespective of graded particle size between 20 nm and 5  $\mu$ m), cotton fabric, and so on. A less crisp spot is given by coarse cardboard, soapstone, aluminium sheet fully etched in hot sodium carbonate solution, and many other materials.

My chief systematic observations are (1) with plane polarized incident light, the spot is polarized in the same plane, although the diffusely reflected light is substantially depolarized; (2) the fraction of total reflected light contributing to retro-reflexion is very small, of order, say,  $10^{-4}$ ; (3) laser (polarized) light shows no behaviour differing significantly from that of ordinary polarized light; (4) many of my observations appear to disagree with Seaney's linear relationship between angular spread of retro-reflexion and reciprocal particle size. For example, the great majority of cubic crystals composing smoked magnesium oxide are only about 200 nm in size, whereas the spot is small and sharp. Perhaps, consistently with observation (2), it could be formed by a minority of much larger crystals which may be present.

Fig. 1. Apparatus for viewing retro-reflexion from diffusing surfaces. A bright spot is formed at X by, for example, white card, and can be viewed as shown. If a small intense arc is used, and stray light screened off, the spot can be bright enough to be seen on an opaque white screen placed at X.

I can trace no explanation of the effect in the literature. I suggest it is a diminutive kind of *heilighenschein*<sup>5</sup>, the bright aura around the shadow of an aircraft cast by the Sun on a forest, as viewed from the plane. This occurs because the spaces between surface leaves make it possible, in that particular direction, to see a maximum area of illuminated leaves deeper down. In the present case I assume that elementary reflexions from deeper elements in the structure are single surface reflexions of specular type, so accounting for observation (1). Furthermore, on this small scale, diffraction would broaden the divergence of these reflexions, the broadening depending at least as much on the size of spaces between individual solid structural elements as on the size of the elements themselves. It is worth noting that, of the total volume occupied by smoked magnesium oxide, 90 per cent consists of air spaces, while blotting paper, which also shows a crisp spot, has a very open structure. Unfortunately one can hardly hope to see, using a microscope and scaled-down version of my apparatus, individual bright elements which may contribute to the retro-reflexion, because the divergence of the latter is insufficient to afford the necessary resolving power.

I thank Mr. Eric J. Gillham for suggesting the use of a beam-splitter, and for stimulating discussions.

## Mechanism of Turbulent Friction Reduction in Pipes by Dissolved Additives

GADD<sup>1</sup> has summarized some of the recent work in friction reduction by high molecular weight additives and concludes that the primary mechanism is a thickening of the laminar sublayer. Investigations of the effect of such additives on pipe flow carried out at West Virginia University support this explanation.

Measurements of the decrease in pressure drop<sup>2</sup> using polyethylene oxide as the additive showed that there is a saturated regime corresponding to maximum reduction in friction. This occurred at relatively low concentrations: 30 p.p.m. for material with an average molecular weight of  $2.3 \times 10^6$  and 20 p.p.m. for a molecular weight of  $4.5 \times 10^6$ . Increasing the concentration had no effect until the concentration became large enough ( $\sim 100$  p.p.m.) to change the viscosity. For these saturated solutions the friction coefficient varied as  $R_e^{-2/3}$  as against  $R_e^{-1}$  for laminar flow and  $R_e^{-1/4}$  for normal turbulent flows (where  $R_e$  is the Reynolds number). Similar results have been obtained by other investigators<sup>3</sup> and it appears that the saturated friction curve is the same for all effective additives. The concentration of additive required to obtain the maximum friction reduction can be considered a measure of the effectiveness of the additive.

Measurements of the velocity distribution<sup>4</sup> gave the surprising result that the velocity distribution with additive present was not intermediate between the laminar and turbulent profiles but was actually fuller than for normal turbulent flow. When plotted in the velocity defect form

$$\frac{u_c - u}{u^*} = f(r/r_0) \quad (1)$$

however, the data for flow with additive agreed with that for normal turbulent flow within the limited accuracy of the measurements. This is strong evidence that the effect of the polymer is on the laminar sublayer. It can be shown<sup>5</sup> that when the velocity defect law is valid, the friction coefficient is given by

$$\lambda = 8 (k + u_w/u^*)^{-2} \quad (2)$$

where  $k$  is a constant.

The results for normal turbulent flow in smooth pipes are fitted by taking  $u_w/u^*$  (the velocity at the junction of the turbulent core and the sublayer) as

$$\frac{u_w}{u^*} = 5.25 \log R_e \times 10^3 \quad (3)$$

and the constant as 10.3. It can readily be seen that increasing  $u_w/u^*$  decreases the friction coefficient and gives a fuller profile.

If the effect of the additive is on the laminar sublayer then it should be possible to reduce the amount of additive needed by injecting the additive through the wall at the pipe inlet. The observation of Davies and Ponter<sup>6</sup> that friction reduction persists when water flows through a pipe previously wetted by additive indicates that diffusion of the additive from the sublayer into the core is relatively slow, so that the required concentration will

be maintained in the sublayer for an appreciable length of pipe.

A possible physical explanation of the mechanism by which the additive affects the laminar sublayer may be found in the work of Deryaguin, who developed the blow off method for investigating the viscosity of thin film. He states<sup>7</sup>: "The results of these studies published so far leave no shadow of doubt that the viscosity in polymolecular boundary layers of polar liquids differs from that of the bulk (being sometimes lower but more frequently higher). On the whole there is a clear tendency for the thickness to increase with increasing length of the liquid molecules. In some cases, that is, that of hexaethoxy-decane, the viscosity is several times higher in a boundary layer about  $0.3\mu$  thick near the wall." Investigations of solutions of additives by Deryaguin's technique might explain the mechanism of friction reduction in terms of the thickness of the anomalous layer and the change in viscosity.

This work was supported in part by a grant from the U.S. National Science Foundation. W. C. and J. C. held National Aeronautics and Space Administration traineeships. The 'Polyox' resin used in the research was supplied by the Union Carbide Corporation.

## Geometry of Condon Loci of Molecular Spectra

It is well known that if the positions of the most intense ( $v'$ ,  $v''$ ) bands of a diatomic molecular spectrum are indicated on the usual Deslandres diagram the axes of which are the upper ( $v'$ ) and the lower ( $v''$ ) quantum numbers involved, then the set of points ( $v'$ ,  $v''$ ) so plotted trace out a set of nested, open-limbed curves called the primary and subsidiary Condon loci, some aspects of the geometry of which have been previously discussed<sup>1,2</sup>. In particular, it was suggested<sup>2</sup> that the position of the primary locus could be predicted from a consideration of those vibrational wave functions for which two respective antinodes are located at the same internuclear separation  $r$ . It was further suggested that the subsidiary loci could be located from a similar consideration of those wave functions for which one primary antinode and one appropriate subsidiary antinode, respectively, lie at the same value of  $r$ . These criteria ensure significant overlap between the two wave functions and thus a relatively large value of the Franck-Condon factor (square of the vibrational wave function overlap integral) which controls all transition probability and intensity parameters of the band.

The vibrational wave function  $\Psi_v(r)$  possesses  $(v+1)$  antinodes which are numbered in pairs inwards from the terminal antinodes. The  $p'$ th antinodes are designated  $r_{p'}^1(p)$  and  $r_{p'}^2(p)$ . The terminal antinodes are similarly designated  $r_v^1(1)$  and  $r_v^2(1)$ . Further,

$$r_{v'}^1(1) < r_{v'}^2(p) < r_e < r_{v'}^2(p) < r_{v'}^2(1)$$

$r_e$  is the equilibrium internuclear separation. It may thus be expected that the primary Condon locus passes through or near those  $v'$  and  $v''$  values which satisfy

$$r_{v'(1 \text{ or } 2)}(1) = r_{v''(1 \text{ or } 2)}(1) \quad (1a)$$

or more simply

$$r'_{(1 \text{ or } 2)}(1) = r''_{(1 \text{ or } 2)}(1) \quad (1b)$$

Similarly, the  $p'$ th subsidiary locus should pass through or near  $v'$  and  $v''$  values which satisfy

$$r'_{(1 \text{ or } 2)}(1 \text{ or } p) = r''_{(1 \text{ or } 2)}(p \text{ or } 1) \quad (2)$$

It is the purpose of this communication to record a recent extensive examination<sup>3</sup> of the ability of equations (1) or (2) to predict the positions of the primary and subsidiary Condon loci for a large number of band systems for which vibrational wave functions and Franck-Condon factors are available.

The three alternatives for the primary locus implied in equation (1) for the case where  $r_e' > r_e''$  are

$$r_1'(1) = r_1''(1) \quad (3a)$$

$$r_1'(1) = r_2''(1) \quad (3b)$$

$$r_2'(1) = r_2''(1) \quad (3c)$$

Fig. 1a and b illustrate (for  $r_e' > r_e''$ ) the three segments of the primary locus predicted by equations (3a)–(3c). Fig. 1a traces (in the  $v$ - $r$  plane) the location of the principal antinodes of wave functions for each of the two potentials involved in the transition. The three vertical lines on it correspond, respectively, to the conditions of equations (3a)–(3c). Fig. 1b represents the corresponding

Fig. 1. Conditions giving rise to primary Condon locus. (a) Pairs of terminal antinodes located at equal internuclear separation. The curves are loci of terminal antinodes in  $v$ - $r$  plane. (b)  $v'$ - $v''$  Deslandres plot from co-location of terminal antinodes. Designations (3a) etc. relate to equations in text.

location of the three segments of the primary locus in the  $v'-v''$  plane.

Possible segments of the  $p'$ th subsidiary locus are those implied in equations 4a-4f which cover all possibilities of equation (2). The cases  $r'_2(1) = r'_1(p)$  and  $r'_2(p) = r'_1(1)$  are excluded by the hypothesis  $r'_e > r''_e$ .

$$r'_1(1) = r''_1(p) \quad (4a)$$

$$r'_1(p) = r''_1(1) \quad (4b)$$

$$r'_1(1) = r''_2(p) \quad (4c)$$

$$r'_1(p) = r''_2(1) \quad (4d)$$

$$r'_2(1) = r''_2(p) \quad (4e)$$

$$r'_2(p) = r''_2(1) \quad (4f)$$

Fig. 2a and b illustrate the situation. Fig. 2a traces in the  $v-r$  plane the location of the principal and  $p'$ th antinodes of the wave-functions for each of the two potentials involved in the transition.

The vertical lines correspond to the respective conditions of equations (4a)-(4f). Fig. 2b illustrates the corresponding possible locations of segments of the  $p'$ th subsidiary locus.

A direct comparison between the Condon loci and the predicted position of the segments has been carried out for many band systems using the parabolic and Morse models of molecular potentials. For the parabolic model, Hermite wave functions are known analytically and have been tabulated by Pillow<sup>4</sup>, while extensive tables of overlap integrals have been computed by Aiken<sup>5</sup>. For Morse potentials, extensive Franck-Condon factor arrays are available<sup>6</sup> together with tabulations of wave functions.

Comparisons were made between loci segment predicted by equations (3a)-(3c) and (4a)-(4f) and the actual loci evident both in computed Franck-Condon arrays and also

in intensity distributions for thirteen representative band systems the  $\Delta r_e$  of which varied from nearly zero (gallium iodide) to 0.4 Å (molecular oxygen). Excellent agreement was found between the location of calculated segments and actual Condon loci in all cases except for those of very small and very large values of  $\Delta r_e$ , for both of which principal contributions are made to the overlap integral from more than one pair of overlapping wave-function loops. The size of each segment and its orientation and position depend largely on  $\Delta r_e$ , and to a lesser extent on other molecular constants.

The subsidiary loci closely follow the location of segments  $a$ ,  $c-d$  and  $f$  when  $r'_e > r''_e$ , for there is additional constructive overlap between many of the wave functions.

## THE SOLID STATE

### Domain Wall Motion in Double Nickel-Iron Films

Middelhoek and Wild<sup>1</sup> have recently measured mobilities for domain wall motion in double nickel-iron alloy which are significantly greater than those reported earlier by Patton and Humphrey<sup>2</sup> for similar films. Both groups have published mobility data for single layer films which are in good agreement<sup>3,4</sup>. In an attempt to clarify the situation concerning double films, mobility measurements have been made for two of Middelhoek and Wild's double films, each with two 400 Å nickel-iron layers (80 per cent nickel) separated by 100 Å of silica, using the technique reported previously<sup>2,4</sup>. For these films, a wall mobility value of  $1.2 (\pm 0.3) \times 10^4$  cm/sec-Oe was obtained. Middelhoek and Wild's mobility of  $4.1 \times 10^4$  cm/sec-Oe for double films (440 Å nickel-iron layers separated by 100 Å of silica) is significantly larger than the present determination. These differences are too large to be explained by the 40 Å difference in nickel-iron layer thickness or the scatter in the data. The differences in mobility determination for similar films from the same laboratory, as measured by different laboratories, can only be due to differences in the experimental technique.

For both techniques, single isolated domain walls are moved across the film using a number of short easy-axis field pulses of known duration and amplitude. Middelhoek's technique uses a large number (about 500) of very short pulses (20-800 nsec). The technique used by Patton and Humphrey<sup>2,4</sup>, on the other hand, uses only a small number (1-50) of longer (10-100 μsec) pulses to produce the wall displacements. Presumably, for sufficiently short pulses, effects involving the wall mass and elastic wall displacements would make the velocity a function of pulse length. If these effects were important, Middelhoek's technique (using shorter pulses) would be expected to yield lower, not higher, mobilities than those reported by Patton and Humphrey. Both authors have, however, reported that the results do not depend on these parameters. For Middelhoek's technique, the wall geometry in the film is controlled by the field itself, produced by a stripline passing over the film. As wall motion proceeds

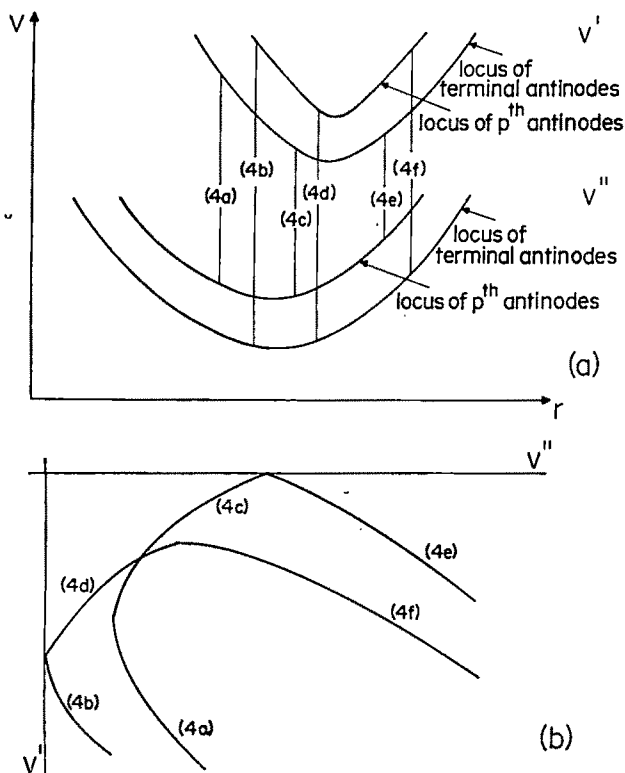

Fig. 2. Conditions giving rise to  $p'$ th Condon locus. (a) Terminal and  $p'$ th subsidiary antinodes at same internuclear separation. The curves are antinode loci in the  $v-r$  plane; (b)  $v'-v''$ , Deslandres plot from co-location of terminal and  $p'$ th antinodes. Designations (4a) etc. relate to equations in text.

additional growth of a zig-zag wall structure occurs at both ends of the wall section under observation, at those points where the stripline field falls below the coercive force. For Patton and Humphrey's technique, the wall geometry is controlled by quality of the film. The easy-axis drive field is produced by a Helmholtz pair and is uniform over the entire film. The wall length must remain approximately constant (limited by the film edge) and no additional nucleation or growth of walls can occur in order for a meaning of mobility determination to be made.

At present, it is not clear why the two sets of mobility data for double films are different. Because the two techniques yield different results even for similar samples from the same laboratory, it appears that the differences result from the measurement technique. Because the mobility data for single layers are in agreement, however, these differences must involve some aspect of the technique peculiar to layered films.

## CHEMISTRY

### Formation of Polycyclic Aromatic Hydrocarbons in Pre-mixed Acetylene-Oxygen Flames

AN investigation has been made of the polycyclic aromatic hydrocarbons associated with the soot in pre-mixed acetylene-oxygen flames operating at a pressure of 20 mm of mercury. The burner, diameter 5.125 in., incorporated a water-cooled porous metal disk and enabled a flat-flame to be stabilized above it with an extended reaction zone. Water-cooled stainless steel grids were inserted into the flame at varying heights above the burner and samples of soot were collected.

At the specified pressure, an acetylene-oxygen ratio of about 0.95 just began to produce soot. Flames employed in the present work corresponded to acetylene-oxygen ratios of 1.2 and 1.5 respectively. The apparent temperatures (uncorrected) measured by means of a silica coated thermocouple probe of platinum and platinum/rhodium (87:13), the wires being 0.008 in. diameter, were

Fig. 1. Flame 1. Temperature of flame versus height above burner surface. 1, Axis of burner; 2, 1.1 in. from axis; 3, 2.0 in. from axis.

Fig. 2.  $\Sigma$  Major polycyclics in soots from flame 1 (O) and 2 (X) versus height above the burner.

Fig. 3. Individual polycyclics in soot, expressed as ratio to pyrene versus height above the burner. Flame 1. O, Chrysene (228)+1,2-benzanthracene (228); +, 2,13-benzfluoranthene (226); X, fluoranthene (202); ●, anthracene (178)+phenanthrene (178). Numbers after names are molecular weights.

recorded at varying heights and the results are plotted for flame 1 (acetylene/oxygen ratio = 1.2) in Fig. 1.

Soot was removed from the collecting grid and extracted for 4 h with chloroform in a Soxhlet apparatus with a stream of nitrogen passing through it to prevent any air oxidation of extracted material. The extract was transferred to a 1 ml. flask using carbon disulphide as solvent.

Previous work in this laboratory had indicated that 12 ft. columns, 0.25 in. diameter, containing 10 per cent 'SE-52' silicone gum rubber on 60-80 mesh 'Chromosorb W' as a stationary phase, were capable of giving good separations of individual polycyclic aromatic hydrocarbons when using an 'F and M 810' research gas chromatograph with temperature programming from 190°-300° C at 4° C/min. Normally, flame ionization detectors were used for quantitative determinations, but for the identification of individual polycyclic aromatic hydrocarbons thermal conductivity detectors were used and the eluted hydrocarbons were isolated by bubbling the effluent helium carrier gas which contained them through spectroscopic grade cyclohexane. Their ultra-violet absorption spectra were then recorded.

Fig. 2 represents a plot of the sum of the concentrations of the principal polycyclic aromatic hydrocarbons found in the soot, namely (anthracene + phenanthrene), methyl phenanthrenes, fluoranthene, pyrene, methyl pyrenes, 2,13-benzfluoranthene, (chrysene + 1,2-benzanthracene) versus height above the burner, for flames 1 and 2. This corresponds to acetylene/oxygen ratios of 1.2 and 1.5 respectively.

The concentrations of a number of polycyclic aromatic hydrocarbons in the soot relative to that of pyrene are plotted against height above the burner for flame 1 in Fig. 3.

Bonne, Homann and Wagner<sup>1,2</sup>, who investigated a similar flame to that used in the present work, found that

the number of soot particles reaches a maximum early in the flame and then slowly decreases, growth in the size of the particles being caused by agglomeration. The particle size as well as the number of particles became nearly constant at heights of more than about 5 cm above the burner. By mass spectrometer investigations, Homann (discussion on "Elementary Steps in Gas Phase Oxidation", University of Liverpool, 1965) later found a number of polycyclic aromatic hydrocarbons containing 5- and 6-membered rings to be present in the burned gas. Such compounds had already been detected in the soluble part of soot<sup>3</sup>. The concentrations of these aromatic compounds were claimed to increase steadily in the burned gas, which suggested that they cannot be important intermediates in the first phase of carbon formation, as otherwise its rate would not decrease while the concentration of these compounds are still increasing.

Our results in Fig. 2 show that between heights of 1 and about 4 in. in the flame there is a gradual increase in the concentration of polycyclic aromatic hydrocarbons in the soot but a considerably greater increase occurs later in the flame at heights of 6–10 in. above the burner. This corresponds to a much lower temperature region than that in which, according to Bonne, Homann and Wagner, most of the soot is formed.

Badger and co-workers in their extensive investigation of the formation of polycyclic aromatic hydrocarbons by pyrolysis have reported that there is an optimum temperature range for the formation of polycyclic aromatic hydrocarbons, for example 660°–740° C in the pyrolysis of *n*-butylbenzene<sup>4</sup>, although some formation occurs at higher temperatures. It must be borne in mind that the residence time in a flame is much shorter than in the pyrolysis experiments.

Assuming that the concentration of polycyclic aromatic hydrocarbons in the soot reflects the state of affairs in the flame, we support the conclusions of Homann. The formation of polycyclic aromatic hydrocarbons appears to occur principally in a lower temperature region of the flame than that corresponding to soot formation, thus also supporting the earlier evidence of Ray and Long<sup>3</sup> that these compounds are not intermediates in carbon formation in the flames investigated.

Of the polycyclic aromatic hydrocarbons pyrene occurs in the greatest concentration in the soot up to approximately 7 in. above the burner after which 1:2-benzanthracene predominates. (Although the gas chromatographic peak represents chrysene and 1:2-benzanthracene unresolved, spectrophotometry of this fraction indicates only a small proportion of the former.) The relative concentrations of individual hydrocarbons change with height above the burner as can be seen from Fig. 3. In this connexion, Lang, Buffleb and Zander<sup>5</sup> have provided illustrations of the formation of higher condensed ring systems by the pyrolysis of relatively low molecular weight polycyclic aromatic hydrocarbons and such processes appear to be occurring in the flame.

This investigation was supported by a grant from U.S. Public Health Service from the Division of Air Pollution.

## Structures of *Tris*-oxalato-complexes of Trivalent Metals

THE *tris*-oxalato-complexes of the general formula  $K_3[M(C_2O_4)_3] \cdot xH_2O$  (I), where *M* can be aluminium, vanadium, chromium, iron, cobalt, rhodium, iridium and several other metals [*x* varies, being 3 for aluminium, vanadium, chromium and iron; 3.5 for cobalt; and 4.5 for rhodium and iridium], have played a leading part in many aspects of co-ordination chemistry during the past 50 years. A great deal of work refers<sup>1</sup> to their spectroscopic behaviour (where they are normally considered as *tris*-chelate compounds), their kinetic behaviour in solution, and, in some cases, their resolution into enantiomers.

Though it has been generally accepted, the assumption of formula (I) as written is not, however, well justified, because a good deal of evidence relates to the importance of the *bis*-chelated form  $[M(C_2O_4)_2(HC_2O_4)(OH)]^{3-}$ , both in the solid state and in solution. The question of the part played by water in the crystal lattice has now been investigated by several methods to attempt to distinguish between salts which are properly formulated as (I), containing water of crystallization, and others, in which the water plays a less obvious part. The racemic potassium salt of the rhodium (III) complex, " $K_3[Rh(C_2O_4)_3] \cdot 4.5 H_2O$ ", is a good example of the latter category; it has been reformulated<sup>2</sup>  $K_6[Rh(C_2O_4)_3][Rh(C_2O_4)_2(HC_2O_4)(OH)] \cdot 8H_2O$  on the basis of broad-line proton resonance measurements.

The salts of the kinetically labile complex anions of aluminium, vanadium and iron have similar structures because they are isomorphous. The racemic complex of chromium (III) is also isomorphous with this series. All have *x*=3. The crystal and molecular structure of a typical member, potassium *tris*oxalatovanadate (III) trihydrate, has been determined by three-dimensional X-ray analysis (using 1,350 independent reflexions) and refined by the method of least squares (*R* is 0.15). The monoclinic green crystals have space group  $P2_1/c$ , *a*=7.81, *b*=20.01, *c*=10.35;  $\beta$ =108° 33', *Z*=4,  $\rho_{calc}$ =2.102,  $\rho_{obs}$ =2.09 g/cm<sup>3</sup>. The complex ion is shown in Fig. 1.

Each vanadium ion is surrounded by three chelating oxalate ions, the complex anion having approximately *D*<sub>3</sub> symmetry. The three molecules of water of crystallization fall into two classes, neither class being strongly hydrogen bonded (the infra-red spectrum shows three bands in the region due to stretching modes of water). All the water is readily lost on heating; the thermogravimetric analysis curve shows a single weight loss at about 110° C, and differential thermal analysis confirms that this process is endothermic.

Fig. 1. The complex anion  $[V(C_2O_4)_3]^{3-}$ . O, Vanadium; ●, carbon; ○, oxygen.

The formulation (I) is thus justified for the trihydrates,  $K_3[M(C_2O_4)_3 \cdot 3H_2O]$ , where  $M$  is vanadium (and, by isomorphism, aluminium, iron and chromium). Crystals of these compounds contain *tris*-chelated complex anions of approximately  $D_3$  symmetry, and distinct water of crystallization. The present results agree well with some earlier crystallographic work. The salt  $K_3[Cr(C_2O_4)_3] \cdot 3H_2O$  was investigated<sup>3</sup> by two-dimensional X-ray analysis, and found to belong to the space group  $P2_1/c$  with a structure similar to that found here for the complex of vanadium. The complex of iron (III) in its potassium salt was also found<sup>4</sup> to contain *tris*-chelated complex ions.

The racemic salts of the kinetically inert transition metal ions cobalt (III) and rhodium (III) are entirely different. They are not isomorphous with the trihydrates of formula (I), nor with each other. Their infra-red spectra and thermogravimetric behaviour differ completely from the cases of the trihydrates. It seems likely that, in the cases of the complexes of cobalt and rhodium (and in the racemic complex of iridium, which is isomorphous with that of rhodium), some of the "water of crystallization" is constitutive (that is, involved in the co-ordination sphere). Further investigations are in progress on the factors influencing the molecular structures of complex metal oxalates.

## IMMUNOLOGY

### Correlation between Net Charge of Antigens and Electrophoretic Mobility of Immunoglobulin M Antibodies

EARLIER we reported that the net electrical charge of rabbit antibodies of the immunoglobulin G class to various natural and synthetic antigens was inversely related to the net electrical charge of the antigens<sup>1</sup>. Thus, under a certain set of conditions, antibodies to acidic antigens were found to predominate in the first chromatographic fraction eluted from diethylaminoethyl-'Sephadex', whereas antibodies to basic antigens were mostly in the second fraction. Immuno-electrophoresis revealed that at pH 8.6, the second fraction moved faster towards the anode than the first fraction. This effect was shown to be independent of the immunological specificity of the IgG antibodies investigated, as the electrophoretic mobility of anti-dinitrophenyl (DNP) antibodies elicited by DNP conjugates of various acidic and basic proteins and synthetic polypeptides was related to the net charge of the macromolecular carrier.

Many differences have been detected between the structural, biosynthetic and biological characteristics of IgM and IgG proteins<sup>2-5</sup>. It was, therefore, of interest to determine whether the effect of the net charge of antigens on the IgG class of antibodies was also characteristic of the IgM antibodies. The preparation in this laboratory of immunoadsorbents using bromoacetyl cellulose permitted the isolation of IgM and IgG antibodies of the same

immunological specificity in a highly pure form<sup>6</sup>. The data presented here show that the net charge of the antigen influenced the electrophoretic mobility of IgM antibodies in a manner similar to that observed for the IgG antibodies.

Randomly bred rabbits were immunized by injecting 5-10 mg of the antigens listed in Table 1, emulsified in Freund's adjuvant at multiple intradermal sites. Purified antibodies were isolated by adsorption from the antisera with immunoadsorbents prepared by the chemical reaction of the respective antigens and bromoacetyl cellulose<sup>7</sup>, followed by acid elution<sup>8</sup>. Anti-DNP immunoglobulins were purified with DNP-human serum albumin cellulose as the immunoadsorbent. Antibodies of the IgM and IgG class were separated by gel filtration using 'Sephadex G-200' (ref. 8). Analytical ultracentrifugation revealed a single component for each class of antibody<sup>9</sup>.

The electrophoresis was carried out in a standard apparatus ('Immuno-for', LKB Produkter, Sweden) using 0.05 molar sodium barbital buffer, pH 8.6, in the electrode tanks and for the preparation of the agar (1.5 per cent special Noble agar, Difco, Michigan). The proteins were separated by applying 220 V, 31 m.amp, to eighteen slides for 100 min. After the electrophoresis the albumin zone of the normal serum, used as a reference for each slide, was located and pierced with a capillary pipette. Goat anti-rabbit immunoglobulin sera were applied to the troughs and, after precipitin arcs had developed, the slides were washed with 0.15 molar sodium chloride and stained with naphthol blue black dye<sup>9</sup>.

The migration of the serum albumin was chosen as the distance between the cathodal end of the precipitin arc of the normal serum IgG and the mark in the gel. The centre of the precipitin arc of the normal immunoglobulins and the individual antibodies was located and the distance determined from this point to the cathodal end of the normal serum IgG. The  $M_r$  values<sup>10</sup> listed in Table 1 were obtained by dividing the distance of migration of the normal and antibody immunoglobulins by the distance of migration of serum albumin. The  $M_r$  for normal IgM was  $0.537 \pm 0.007$  and for normal IgG was  $0.270 \pm 0.007$ . All samples were examined in duplicate or triplicate.

Table 1. RELATIVE  $M_r$  VALUES OF RABBIT IgM AND IgG ANTIBODIES

Immunogen	$M_r$ of IgM		$M_r$ of IgG	
	Normal serum	Antibody	Normal serum	Antibody
(A) Acidic				
(1) Diphtheria toxoid	0.51	0.43	0.24	0.14
(2) (T, G)-A-L <sup>1</sup>	0.53	0.43	0.25	0.12
(3) DNP-(T, G)-A-L <sup>1</sup>	0.51	0.41	0.24	0.12
(B) Basic				
(1) Lysozyme	0.55	0.54	0.26	0.24
(2) Ribonuclease	0.56	0.56	0.25	0.25
(3) Uridine-A-L <sup>11</sup>	0.54	0.55	0.25	0.27
(4) DNP-poly-L-lysine <sup>1</sup>	0.55	0.53	0.26	0.28

IgM and IgG antibodies, elicited by the immunogens listed in the first column, were isolated from immune sera with immunoadsorbents prepared using bromoacetyl cellulose<sup>8</sup>. Individual immunoglobulin samples were electrophoresed with a normal serum specimen on the same slide. Following the electrophoresis the albumin zone of normal serum was located and its position marked in the agar. Goat antiserum to rabbit IgM or the  $F_2$  fragment was used to develop the precipitin arcs. The distance between the cathodal edge of the normal serum IgG and the albumin was determined. The  $M_r$  values of the antibodies and their normal serum counterparts were calculated by dividing the distance between the middle of the precipitin arc of these immunoglobulins and the cathodal edge of the normal serum IgG by the distance of the albumin migration.

The results of the immuno-electrophoretic runs are summarized in Table 1. Two representative patterns of IgG and IgM antibodies, elicited by the acidic synthetic antigen (T, G)-A-L<sup>1</sup> and by the basic uridine-A-L<sup>11</sup>, are shown in Fig. 1. It is clear from Fig. 1 and from the  $M_r$  values in Table 1 that the electrophoretic mobility of both the IgM and the IgG antibodies depends on the net charge of the antigens. The centre of the precipitin arc of the anti-(T, G)-A-L IgG preparation (Fig. 1) was chosen in the region where the precipitin arc was most intense. This region represents 79 per cent of the total IgG antibody<sup>1</sup>.

Fig. 1. Immunoelectrophoresis of purified IgM (top) and IgG (bottom) anti-uridine-A—L (a) and anti-(T, G)—A—L (b) antibodies. The normal serum was placed in the upper hole and the antibody applied to the lower hole of each slide. The proteins were electrophoresed and the albumin zone of the normal serum pierced with a capillary pipette (□). A goat anti-rabbit immunoglobulin serum was added to the trough and the slides washed with 0.15 molar sodium chloride and stained after the precipitin arcs were developed.

The inverse relationship between the charge of the antigen and the electrophoretic mobility of the IgM as well as the IgG antibodies was also demonstrable for the basic proteins, ribonuclease and lysozyme, and the acidic protein, diphtheria toxoid. As previously reported<sup>1</sup>, this difference in electrophoretic mobility was independent of the specificity of the antibody. Thus, IgM antibodies with anti-DNP specificity had their electrophoretic mobility directed by the net charge of the carrier molecule, similarly to the IgG anti-DNP antibodies.

Antibodies isolated from individual rabbit sera yielded the same results as were observed with the pooled samples. The electrophoretic mobility also did not change when antibodies were isolated at different times during the course of immunization.

It is apparent from the data presented here that the effect of the charge of an antigen on the electrophoretic mobility of the antibodies it elicits is demonstrable not only in the IgG class but also in the IgM class of antibodies. The simplest explanation would seem to be that there is a process of selection by the antigen, at cellular or subcellular level, of the loci at which the antibody is synthesized<sup>1</sup>. One possibility may be that an initial step in the biosynthesis of the antibody is the reaction of a charged area on the antigen with some complementary receptor sites. These sites may be complementary either to antigenic specificity determinants or to other areas of the antigenic molecule.

### Apparent Absence of Immunological Cross-reactivity between Human and Simian Gonadotropic Hormones as determined by Radioimmunoassay

It has been reported that crude monkey luteinizing hormone (LH) and follicle stimulating hormone (FSH) preparations cross-react immunologically with an antiserum to human FSH as measured by the haemagglutination inhibition technique<sup>1</sup>. Professor Carl Gemzell (personal communication) was also able to show, using the same technique, that a partially purified rhesus monkey pituitary LH preparation, supplied by us, reacted with an antiserum to human chorionic gonadotropin (HCG). This information, together with the well established immunological and physiological similarities between human and simian growth hormone<sup>2</sup>, prompted us to attempt the development of radioimmunoassays for the measurement of circulating LH and FSH in the rhesus monkey using the more readily available human gonadotropins as antigens.

The interaction of purified preparations of human and simian (rhesus monkey) luteinizing hormone and follicle stimulating hormone with antibodies against several human gonadotropins was studied with a modification of the radioimmunoassay devised for insulin by Herbert *et al.*<sup>3</sup>. Human pituitary LH (HLH) and human pituitary FSH (HFSH) were iodinated with iodine-131 according to the method of Greenwood *et al.*<sup>4</sup>. The HLH had a biological activity of 5.3 times NIH-LH-S1 in the ovarian ascorbic acid depletion assay of Parlow<sup>5</sup>. The HFSH had 156 times the potency of NIH-FSH-S1 as measured by the assay of Steelman and Pohley<sup>6</sup>. Antisera produced in rabbits against four gonadotropin preparations were used: HCG (7,000 IU/mg), HCG (2,600 IU/mg), pituitary HLH (same relative potency as NIH-LH-S1) and pituitary HFSH (relative potency of fifteen times NIH-FSH-S1). Antigen-antibody reactions were carried out for 5 days at 5° C in a barbitone buffer containing bovine serum albumin. Iodinated hormone bound to antibody (B) was separated from free iodinated hormone (F) by adsorption of the latter to charcoal coated with dextran.

Three different simian pituitary LH (SLH) preparations with biological activities of 0.06, 0.3 and 0.4 times NIH-LH-S1 were tested for their ability to compete with HLH-<sup>131</sup>I for the various antibodies to HCG and HLH. One simian pituitary FSH (SFSH) preparation with a biological activity ten times NIH-FSH-S1 was similarly tested against HFSH-<sup>131</sup>I using the HFSH antiserum. Each simian gonadotropin preparation was assayed, at least twice, against the appropriate antiserum. The amounts of the SLH and SFSH preparations are expressed in terms of their biological activity relative to that of the HLH and HFSH preparations with which they are compared rather than in terms of weight in order to

eliminate the extent of purification as a variable (for example, see Fig. 1).

When HLH was reacted with the two HCG antisera or with the HLH antiserum, a significant displacement of the radioiodinated HLH from the antibody was observed with 0.1  $\mu\text{g}$  of the hormone. Unfortunately, however, amounts of SLH as high as 36  $\mu\text{g}$  equivalents of HLH produced very little displacement of iodinated HLH from the antibody (Figs. 1 and 2). Varying dilutions of rhesus monkey pituitary homogenate (1/160–1/10 of a single gland) also failed to produce a significant displacement of the iodinated HLH. Identical results were obtained with homogenates of squirrel monkey pituitary glands. Similarly, SFHSH at a level of 32  $\mu\text{g}$  equivalents of HFSH failed to effect a significant displacement of the iodinated HFSH from the HFSH antibody while 0.1  $\mu\text{g}$  of the HFSH produced a significant depression of the ratio of  $B:F$  (Fig. 3).

These results demonstrate the relative absence of immunological interaction between the rhesus monkey pituitary gonadotropins and antibodies produced against HLH, HFSH or against HCG. Whether larger amounts of SLH and SFHSH than those used in the present investigation would at some point give a dose-response curve with the human antibody has not been determined. The data presented, however, lead to the conclusion that the successful application of radioimmunoassays to the measurement of circulating gonadotropins in the rhesus monkey will require antisera against FSH and LH isolated from this species and that antigens of human pituitary and chorionic origin cannot, unfortunately, be used for this purpose.

In contrast to the relative absence of immunological cross-reaction between human and simian gonadotropins, ovine, equine and human luteinizing hormone preparations show full interstitial cell stimulating activity in hypophysectomized male rhesus monkeys<sup>7</sup>.

The apparent discrepancy between the results of the haemagglutination inhibition assay and the radioimmunoassay in assessing the immunological cross-reactivity of human and simian gonadotropins cannot be fully evaluated at the present time.

We thank Dr. A. F. Parlow for the LH antiserum and for the bioassays of our simian and human gonadotropin preparations, and Dr. B. B. Saxena for the HFSH antiserum.

Fig. 1. Relative affinity of a human pituitary LH preparation and of three simian LH preparations for an antibody to HCG as measured by the displacement of  $^{125}\text{I}$ -HLH from the antibody. This displacement is expressed as the ratio of antibody-bound ( $B$ ) to free ( $F$ ) radioactivity.  $\Delta$ , HLH;  $\bullet$ , SLH;  $\circ$ , SLH;  $\blacktriangle$ , SLH. The numerical values on the abscissa represent the biological activity contained in the simian preparations expressed in terms of the amounts of the HLH containing equivalent biological activity. For example, 36  $\mu\text{g}$  equivalents of  $\circ$  represent 500  $\mu\text{g}$  of this preparation containing the same biological activity as 36  $\mu\text{g}$  of the HLH preparation.

Fig. 2. Relative affinity of HLH and of two SLH preparations for an antibody to HLH. Symbols as in Fig. 1.

Fig. 3. Relative affinity of HFSH ( $\circ$ ) and of SFHSH ( $\bullet$ ) for an antibody to HFSH.

This investigation was supported in part by a U.S. Public Health Service fellowship from the National Institute of Child Health and Human Development to J. D. N. and by grants from the U.S. National Institutes of Health and from the Ford Foundation.

### Further Studies on the Adjuvant Principle of Pertussis Vaccine for the Mouse

We have already presented evidence that the capacity of pertussis vaccine to enhance antibody formation in mice to unrelated protein antigens is labile to heat and therefore, contrary to the view of many workers, cannot be attributed

to the heat-stable endotoxin of the pertussis organism<sup>1</sup>. We postulated that the protective antigen is not only capable of sensitizing mice to histamine but may also be responsible for this typical adjuvant effect associated with pertussis vaccine. We further proposed that the autonomic nervous system may be involved in an enhancement of the immune response in mice mediated by pertussis. The object of this communication is to describe certain experiments designed to determine the validity of these postulations.

The experiments involve the final precipitate and supernatant of our fractionation scheme<sup>2</sup> formed by adding ammonium sulphate to the clarified vaccine lysate to 35 per cent saturation. We have shown that this precipitate contains most of the immunogen and the histamine sensitizing factor (HSF) whereas the supernatant, although it contains the bulk of the organic bacterial substance, has only small amounts of these activities. The object of the experiment was to compare these two fractions in mice with respect to all three activities—immunogenicity, histamine-sensitization, and adjuvance for tetanus toxoid. A graded three-dose design based on non-dialysable nitrogen, identical for each activity, was adopted for their biometric estimation. The dosage for "precipitate" was selected to span the previously determined median sensitizing dose of HSF. These doses were 2.3, 6.9 and 20.7  $\mu$ g nitrogen. The highest feasible dose of "supernatant", constrained by volume and toxicity considerations, was about ten times the highest "precipitate" dose, and was scaled down by half instead of by one third. Thus this dosage was 56, 112, and 224  $\mu$ g nitrogen. The mouse intracerebral immunogenicity test and the HSF test were described earlier<sup>2</sup>. The test for adjuvance involved intraperitoneal injection of groups of ten mice with the three dosages of the pertussis fractions, and subcutaneous injection of all these mice with the constant dose of 5 Lf of fluid tetanus toxoid. One group of mice received toxoid only and another group served as uninoculated controls. All mice were challenged in 7 days with an intramuscular injection of 2 minimum lethal doses of tetanus toxin. Observation of the time of death and symptoms was scored by a modification of the method of Ipsen<sup>3</sup>. The mean score of the mouse group expressed as a percentage of the highest possible score comprised the response metameter, designated "percentage of immunity".

Table 1. PARALLEL FRACTIONATION OF THE IMMUNOGENIC, THE HISTAMINE SENSITIZING AND THE ADJUVANT ACTIVITIES OF PERTUSSIS VACCINE

Pertussis vaccine fraction	Mouse dose ( $\mu$ g N)	Immunogenicity (survival rate)	Histamine sensitization (death rate)	Adjuvance (mean per cent immunity for 10 mice, 5 Lf tetanus toxoid each)
35 per cent SAS supernatant	56 112 224	1/11 0/13 2/11	0/16 0/16 3/16	30 38 33
35 per cent SAS precipitate	2.3 6.9 20.7	6/10 6/10 10/10	3/16 11/15 14/16	32 62 72
Controls	None	0/10	0/15	0
Toxoid only	None	—	—	37

The results are given in Table 1 in terms of mouse survival rates for the immunogen, death rates for histamine sensitization, and percentage of immunity for adjuvance. It is apparent that the supernatant showed a very low level for all three of these activities. At the highest dose administered, the survival rate for intracerebrally challenged mice was only two in eleven, the death rate from histamine challenge only three in sixteen, and the apparent tetanus toxoid immunity did not differ significantly from that of mice receiving toxoid alone. On the other hand, the groups receiving "precipitate" in nitrogen dosage ranging from 1/100 to 1/10 that of the highest "supernatant" dosage showed fair to good dose-response regression for all three activities. These results demonstrate "parallel fractionation" of the activities in question which, when considered in conjunction with previous reports that these activities are labile to 100° C heat for 30–40 min<sup>1,4,5</sup> and

that at least two of them, the immunogen and the HSF, can be inactivated by proteolysis<sup>6-7</sup>, suggest that a single substance is implicated.

Fishel *et al.*<sup>8</sup> have suggested that blockade of the  $\beta$ -adrenergic receptors of the autonomic nervous system may be the mechanism by which pertussis vaccine enhances the susceptibility of mice to histamine and serotonin. We have suggested that this may also be so with vaccine enhancement of peptone shock<sup>9</sup>. Fishel *et al.*<sup>10</sup> have demonstrated a converse phenomenon; namely, that injection of an  $\alpha$ -adrenergic blocking agent, dibenzyline, cancelled the capacity of vaccine to increase sensitivity to some of these stresses. After failing to demonstrate adjuvance when the  $\beta$ -agent, propranolol, is substituted for vaccine, possibly because it is metabolized before it can influence the prolonged course of the primary immune response, we decided to attempt the converse type of experiment in relation to adjuvance. We were successful and repeated the experiment.

A group of sixty mice was injected subcutaneously with 1 Lf of tetanus toxoid, and a similar group with 5 Lf. Sub-groups of twenty mice were at the same time injected intraperitoneally with: (1) pertussis vaccine ( $19 \times 10^9$  cells in 1 ml.); (2) the same plus 1 mg dibenzyline in the contralateral site; (3) no injection additional to the toxoid.

A group of twenty mice was set aside as uninoculated controls. After 7 days half of each group of mice was challenged by intramuscular injection of 2 minimum lethal doses of tetanus toxin, and 7 days later the remaining half was challenged with 10 minimum lethal doses. A scoring system appropriate for each challenge was applied to survival time and symptoms and the percentage immunity calculated as already described. The results are shown in Fig. 1. It is apparent that the  $\alpha$ -blocking agent, dibenzyline, partially suppressed the adjuvance of pertussis vaccine, in the same way as the findings for other activities. In a secondary experiment of similar design we found that dibenzyline partially suppressed the immune response of mice to tetanus toxoid given without an associated pertussis vaccine injection.

Recently, Floersheim has reported that dibenamine, a haloalkylamine  $\alpha$ -adrenergic blocking agent closely related chemically to dibenzyline, could depress the tuberculin reaction in sensitized guinea-pigs<sup>11</sup>. Obviously, it is difficult to demonstrate that these apparent immunosuppressive effects result exclusively from the neurologic blocking activities of the molecule, rather than from some other property. Both dibenamine and dibenzyline, for

Fig. 1. Partial suppression by dibenzyline of the adjuvant effect of pertussis vaccine for the immune response of mice to 1 and 5 Lf doses of tetanus toxoid. Each point represents the mean response of ten mice.

example, are known to have antihistaminic effects, and to bear certain chemical resemblances to the nitrogen mustards. Hadnagy *et al.*<sup>12</sup> showed, however, that antihistaminics had no effect on the formation of antibodies. Moreover, whereas the mustard alkylating agents can suppress the immune response of rabbits, Rosenblatt and Johnson found that dibenzylamine did not depress the production of antibodies in that species<sup>13</sup>. In fact, the haloalkylamine blocking agents have few effects in laboratory animals that cannot be attributed to their capacity to block the  $\alpha$ -adrenergic receptors of the autonomic nervous system<sup>14</sup>. One might suggest that the observed immunosuppression might be non-specific in nature or a function of a "generalized toxicity", but it should be noted that many drugs, even when given in near lethal doses, have no effect on the immune response<sup>15,16</sup>.

Several investigators have recently reviewed the altered responses induced in mice and rats to a variety of stresses or stressor agents by pertussis vaccine<sup>17-19</sup>. We propose that the substance responsible is the immunogen itself and that many, if not all, of these reactions are primarily mediated through autonomic nervous mechanisms.

We thank E. J. Broderick and A. Pellegrino for technical assistance in this investigation, which was supported by a U.S. Public Health Service research grant from the National Institute for Allergy and Infectious Diseases through the Massachusetts Health Research Institute.

### Variation in Tolerance Dose Requirements as related to Heterogeneity of the Immune Response

By varying widely the dose of a protein antigen it is possible, in a given system, to vary the response to this antigen from formation of both IgM and IgG antibodies (in the medium dose range<sup>1</sup>) to lack of formation of either type (repeated massive doses). In between, a regimen of antigen administration can be found which stimulates the formation of IgG and not of IgM. This dissociation is reflected in the cellular changes involved.

Seven to eight week old chickens were immunized by intravenous injection of commercial human serum albumin (HSA). The titre of antibodies was evaluated by means of passive haemagglutination with diazobenzi-

dine-conjugated erythrocytes. Distinction between IgM and IgG antibodies was based on specific inhibition by 0.2 molar 2-mercaptoethanol of the former<sup>1</sup>. The cellular response was followed in spleen imprints by the indirect immunofluorescent method of Coons. Counts of antibody containing cells (ACC) were made from 50-100 microscope fields and standardized for fifty fields (about  $5 \times 10^4$  cells). The morphological classification followed the accepted convention<sup>2</sup>; large blast cells were omitted from differential counts. Details and representative examples of the cell types have been given elsewhere<sup>3</sup>. The capacity of the immunofluorescent method employed to detect intracellular antibodies even in the presence of a high level of circulating antigen has already been demonstrated<sup>3</sup>.

Four chickens were killed on each of several days after immunization with various doses of HSA, and the antibody in their serum and spleen was examined as described here. The results are summarized in Fig. 1.

After a relatively small dose (5 mg of HSA/kg of body weight) the first ACC appear after 48 h, their number increases exponentially and after reaching a peak declines rapidly (open circles). During the first phase the majority of ACC are small immature cells with a narrow rim of cytoplasm, mostly distinguishable as lymphocytes. In the succeeding two phases immature and mature plasmocytes appear and gradually predominate. During the exponential phase, serum antibodies are of the IgM type (open triangles), whereas the IgG type (solid triangles) coincides with the appearance of plasmocytes.

With doses more than 2,000 mg, the picture is different. After a dose of 2,500 mg, ACC do not appear until on the fourth day; their number increases slowly to maximum of only about ten ACC per fifty fields (solid circles). Furthermore, the cells are exclusively plasmocytes. The serum antibody is only IgG, and IgM antibodies are absent<sup>1</sup>.

An experiment was carried out to inhibit the immune response completely. If an initial dose of 2,000 mg of HSA is followed by daily doses of 1,000 mg, no ACC appeared in twelve chickens examined on days 4, 7 and 12 (solid squares).

To find whether in animals showing no IgM antibody response its production is totally inhibited, a corresponding group of chickens was injected with a similar dose of 2,500 mg and challenged 7 weeks later with 10 mg. In this group also the IgM antibodies were almost completely absent, even though there is a marked IgM antibody response to 10 mg of HSA in chickens which had received no previous injection or were pretreated with lower doses (0.5-50 mg).

Fig. 1. Response after 5 mg of HSA. —○—, Log number of antibody containing cells (ACC); columns, mean percentage of given cell types (white column, lymphocyte cells, black column, plasmocytes); —△—, values of log titre of IgM (—△—) and IgG (—▲—) antibodies; —●—, log number of ACC after a dose of 2,500 mg (all are of plasmocyte type); —■—, log number of ACC after repeated massive doses (no response).

During the exclusively IgG response elicited by large amounts of antigen the initial exponential proliferation of antibody producing cells is absent, even though it occurs typically, and parallels the serum IgM antibody titre, when both types of antibodies are formed. The complete suppression of any IgM response was confirmed by its absence even when a secondary anamnestic response of IgG type could be induced.

We found, as before<sup>5</sup>, that a much smaller amount of antigen (less than 500 $\gamma$  of HSA) induces the formation exclusively of IgM antibodies; it seems that the IgM response has a low threshold both for induction and inhibition compared with the IgG response, which was only inhibited by repeated massive doses of antigen.

The cellular changes observed probably indicate a functional separation of the IgM and IgG responses. The early phase of differentiation of antibody-forming cells (morphologically of lymphocyte character), which coincides with the IgM response, is possibly accomplished by cells already capable of reacting with antigen at the time of immunization. It may represent a primitive regulatory stage in the development of immunity. The direction of differentiation and the recruitment of further cells to this population may be controlled by the concentration of antigen. This possibility is suggested by the finding<sup>3</sup> that a series of massive doses given during the development of response to a small dose affects proliferation and accelerates differentiation to plasmocytes; here again, the IgG type of response is less easily inhibited by such additional doses than the IgM response.

## CYTOLOGY

### Chromosome Deterioration in Ageing Eggs of the Rabbit

COITUS-INDUCED ovulation in the rabbit ensures that fertilization of nearly all eggs is initiated within 2 or 3 h of their arrival in the fallopian tube. When ovulation was induced by hormone injection, and coitus permitted at the time of ovulation (10 h after injection), fertilization began about 5 h later and continued for a further 3–5 h, eventually involving a little over 70 per cent of the eggs<sup>1</sup>. As a result, therefore, of the delay in the time of coitus, eggs underwent 6 or 7 h ageing before fertilization was initiated; fertilization nevertheless occurred in all but about 30 per cent of eggs. Despite this relatively small drop in fertilization rate there is evidence that fertility in the rabbit is seriously impaired by the delay of coitus. Chang<sup>2</sup> observed that 60 per cent of eggs failed to implant and that more than half the implanted embryos died before term, and Hammond<sup>3</sup> recorded an 80 per cent reduction in the mean number of young born. To some extent, the reduced fertility can be attributed to the occurrence of polyspermy and polygyny, conditions that lead to the highly lethal state of triploidy in the embryo, but this would not account for embryo loss of more than about 16 per cent<sup>4,5</sup>.

Observations were made on unfertilized eggs and on blastocysts. The unfertilized eggs were recovered at 3 and 7 h after gonadotrophin-induced ovulation; they were examined in the whole state, after fixation and staining under a coverslip. Blastocysts were recovered on the sixth day from rabbits which had been artificially inseminated at the same time that they received an injection of human chorionic gonadotrophin ("normal insemination") and also from rabbits that had been inseminated 8 h after the injection ("delayed insemination"). (With the latter time relations, it is estimated on the basis of previous work<sup>1</sup> that fertilization began 3–7 h after ovulation.) The blastocysts were prepared for karyotype analysis by a modified blood-leucocyte technique. In addition, implanted embryos were recovered at 10 days of pregnancy; the cells were disaggregated with protease and karyotypes again analysed.

Thirty-four eggs from four rabbits were recovered 3 h after ovulation; all exhibited metaphase chromosomes of normal appearance, arranged individually and in a regular manner at the equator of the spindle. Sixty-seven eggs from eight rabbits were recovered 7 h after ovulation. In only twenty-nine eggs could the chromosome group be regarded as normal; twenty eggs had chromosomes that were plainly pycnotic, and coalescing to different degrees, and in eighteen eggs there were signs of chromosome scatter with one, two or even three chromosomes detached from the rest of the group (Fig. 1).

Eleven rabbits were killed on the sixth day after normal insemination. These yielded 81 blastocysts, or 7.4 blastocysts per rabbit. Fourteen rabbits killed after delayed insemination provided 52 blastocysts, or 3.7 blastocysts per rabbit.

Chromosome counts, on from eight to thirty-six spreads for each embryo, were made on seven blastocysts arising from normal insemination and sixteen from delayed insemination. The blastocysts from normally inseminated rabbits all gave counts that were predominantly diploid ( $2n=44$ ), but of which 26 per cent were hypodiploid (38–43). Cells from the 16 blastocysts recovered after delayed insemination, however, yielded 63 per cent hypodiploidy. On the other hand, when the 10-day implanted embryos were examined, results obtained in 23 embryos arising from normal insemination were similar to those in 19 embryos from delayed insemination, hypodiploidy being shown by 33 and 23 per cent, respectively, of the counts made. Thus, though the proportion of hypodiploid cells in the delayed insemination group appeared to be elevated at 6 days, the difference had disappeared in the implanted embryos. Triploidy was evident in two 10-day embryos from normal insemination and in five from delayed insemination.

The findings described here showed that (a), by so short a time as 7 h after ovulation, dispersal or pycnosis had taken place among the second metaphase chromosomes in nearly 60 per cent of unfertilized rabbit eggs; and (b),

Fig. 1. a, Normal second metaphase chromosome group, at 3 h after ovulation; b, group showing break-up of the spindle and dispersal of chromosomes 7 h after ovulation.

when fertilization began 3–7 h after ovulation, because of delayed insemination, many embryos died during cleavage and the number of blastocysts at 6 days was reduced by half. It is inferred that the chromosome derangements seen in eggs at 7 h after ovulation attested to ageing effects that were responsible for considerable preimplantation losses. Most of the faulty embryos were thus apparently eliminated, and there was no evidence that ageing of the eggs produced errors of chromosome number, other than triploidy, in post-implantation embryos.

## MICROBIOLOGY

### *In vitro* Growth of *Plasmodium knowlesi* and *P. falciparum*

IMMUNOLOGICAL investigations of the malaria parasite have indicated that effective protective immunity is acquired only against the erythrocytic parasites as they reach maturity. It has been shown<sup>1,2</sup> that chronic malarious sera only agglutinate the mature schizont and that the most effective antigen is derived from the mature erythrocytic form<sup>3</sup>. Gel precipitin reactions have also shown that stronger reactions are obtained against schizont rather than trophozoite antigen of *P. falciparum* when these are diffused against immune sera<sup>4</sup>. Furthermore, passive transfer of acquired immunity is more effective against mature than immature forms<sup>5</sup>.

In some species of malaria parasite, mature erythrocytic stages can be collected from the peripheral circulation but in *P. falciparum* this is not possible because the erythrocytic cycle is concluded in the deep tissues. The only source of parasite antigen has been the collection of schizonts from infected placentae. An obvious prerequisite for large scale investigations of acquired immunity to *P. falciparum* is a relatively simple technique whereby trophozoites obtained from the peripheral blood can be grown to the schizont stage *in vitro*. This paper reports the use of a simplified method for the *in vitro* growth from ring to schizont stage of malaria parasites. Initially *P. knowlesi* was used as a model for the later experiments with natural infections of *P. falciparum* in The Gambia, West Africa.

The medium was a modification of that developed in the Harvard laboratories<sup>6</sup>, with the number of stock solutions reduced to four (solution I, balanced salt solution<sup>6</sup>, solution II, glucose-acetate concentrate<sup>7</sup>, solution III, vitamin concentrate<sup>8</sup>, and solution IV, purines and pyrimidines<sup>8</sup>). The purines and pyrimidines were added at a concentration ten times greater than that of the original medium<sup>8</sup>. Folic acid and vitamin B<sub>12</sub> were added to the vitamin concentrate at a concentration of 100 µg/l.<sup>9</sup> and ascorbic acid was added fresh to the final medium at a concentration of 5,000 µg/l. The amino-acid source was lactalbumin hydrolysate at a final concentration of 0.75 per cent<sup>10</sup>. Reduced glutathione was added to the medium at a concentration of 0.1 per cent. Penicillin was added to give a final concentration of 50 U/ml. and phenol red indicator as 0.2 ml. of a 0.1 per cent solution/100 ml. of medium. The final medium

was sterilized by 'Millipore' filtration and the pH adjusted to 7.4 by bubbling through carbon dioxide.

Infected blood, containing ring stage parasites, was taken aseptically by cardiac puncture from monkeys experimentally infected with *P. knowlesi* and intravenously from Gambians naturally infected with *P. falciparum*. The blood was mixed with sterile 1:1,000 heparin/Ringer in the ratio of one part of heparin/Ringer to ten parts of blood. Initially 4 oz. screw capped medicine flats were used as culture vessels, containing 3 ml. of medium. The bottles were filled with 5 per cent carbon dioxide/95 per cent air mixture to equilibrate with the medium and 1 ml. of heparinized blood added to give a final parasite density of 5,000–50,000 parasites/mm<sup>3</sup> and an erythrocyte density of approximately 1.0–1.5 × 10<sup>6</sup>/mm<sup>3</sup>. Growth of the parasites was evaluated by observing the appearance of the parasite in thin smears, fixed in methanol and stained in Giemsa. Samples were taken from the cultures at the beginning of the experiment and at the end of the incubation period, usually 24 h. Differential counts were made of 200 parasites found in successive microscope fields. A parasite was called a schizont if it possessed three or more nuclei and irrespective of whether it had reached the segmenter stage.

With synchronous *P. falciparum* infections, between 70 per cent and 90 per cent of large ring stages (Fig. 1), taken from the host before their disappearance from the peripheral circulation, developed into schizonts, possessing three to twenty-four nuclei (Fig. 2). The number of abnormal forms was 3 per cent. When very small rings were inoculated into the medium the period of incubation required for growth to mature schizonts was increased to 36–48 h and development was less synchronous. A lower percentage of schizonts, 30 per cent to 50 per cent, were obtained after 36 h of incubation and an increase in the abnormal forms up to 10 per cent was observed. The

Fig. 1. Culture (0 h) ring-stage of *P. falciparum* (× 700).

Fig. 2. Culture (24 h) schizont of *P. falciparum* (× 700).

decrease in the yield of schizonts after this longer incubation period was probably caused by the depletion of glucose by the parasites with the subsequent increase in lactic acid and drop in pH in the cultures<sup>11</sup>. A similar effect was observed during a 24 h incubation period with parasite densities of 40,000–50,000/mm<sup>3</sup>. In experiments with *P. knowlesi*, this was shown to be partially overcome by increasing the ratio of medium to parasitized cells from 3:1 to 6:1.

For large scale work involving *P. falciparum* 1 l. bugged Erlenmeyer flasks, containing 25 ml. of medium and 8.3 ml. of heparinized blood, were used. After 24 h incubation consistently good results were obtained with up to 90 per cent of the parasites reaching the schizont stage with < 3 per cent abnormal forms.

It has previously been noted<sup>11,12</sup> that in culture the maturing *P. falciparum* parasite causes the host erythrocyte to become progressively more "sticky" with the subsequent formation of clumps. This was observed in eight out of ten experiments using blood taken from patients more than 3 yr old. Agglutination, however, was absent in two experiments performed with parasitized blood taken from patients approximately 6 months old. The clumping of parasitized cells may be due to either the transfer of agglutinins or histones<sup>13</sup> from the host's serum into culture or to a fibrinogen effect<sup>14</sup>. Agglutination was prevented by replacing the host serum with normal AB serum after thorough washing of the erythrocytes in the medium (one experiment). By using this culture method, it is possible to obtain large numbers of schizonts which can be used to extend investigations on metabolic and antigenic problems in human malaria.

I thank Dr. I. A. McGregor of the M.R.C. Laboratories, Fajara, The Gambia, for his help and for permission to work in his laboratories where the *P. falciparum* experiments were performed. This work was supported by a grant from the World Health Organization.

### Metabolic Activity of Purified Suspensions of *Rickettsia rickettsi*

THE independent metabolic activities of some of the obligate intracellular bacteria, such as rickettsiae and chlamydiae<sup>1</sup>, have been extensively investigated<sup>2</sup>. Such work has rarely included *Rickettsia rickettsi*, the agent of Rocky Mountain spotted fever, because of the difficulty of obtaining sufficient material of adequate purity and stability. The only data on respiration of *R. rickettsi* are those given in a preliminary report by Price<sup>3</sup>, who carried out his experiments with the collection from several thousand infected yolk sacs and tested the micro-organisms immediately after the final step of purification.

The present work was prompted by the opportunity that now exists to compare the biochemical activities of

*R. rickettsi* with those of other nutritionally fastidious bacteria and by the progress in biochemical technology which has occurred during the 13 yr since the report by Price. We have shown that *R. rickettsi* is amenable to relatively simple methods of purification and investigation. Its metabolic activity resembles that of typhus rickettsiae.

Optimal yield of *R. rickettsi* and greatest specific metabolic activity were obtained by following the recommendations of Stoenner *et al.*<sup>4</sup>: yolk sacs of chick embryos, 4–5 days old, were inoculated with sufficient rickettsiae (Bitterroot strain) to kill most embryos in 4–5 days. The eggs were incubated at 33.5° C for 6–7 days and the yolk sacs were collected 36–48 h after the death of the embryos. The initial suspending diluent was SP 25 (sucrose 0.25 molar, potassium phosphate buffer 0.02 molar, pH 7.0). Glutamate, included in the common rickettsial diluent SPG (ref. 5), was omitted because of the report<sup>4</sup> that it adversely affected the virulence of *R. rickettsi* for the chick embryo. The yolk sacs suspended in SP 25 were maintained at –70° C until they were processed further.

The host cells were macerated with glass beads and the rickettsiae were purified by a procedure adapted from those commonly used for agents grown in yolk sac<sup>6,7</sup>. Host cell components were eliminated by cycles of high and low speed centrifugation, adsorption on to 'Celite', precipitation by bovine plasma albumin, and digestion with the proteolytic enzyme 'Pronase'. When partially purified micro-organisms, suspended in diluent KSC (0.15 molar potassium chloride, 0.015 molar sodium citrate, pH 7.0), were treated with 0.1 per cent 'Pronase' for 1 h at 25° C, their infective and metabolic activities were unaffected, although the remaining host components were removed. 'Pronase' or trypsin was not applied during early steps in the purification procedure, because of the experience with typhus rickettsiae (unpublished results of E. Weiss) which indicated that rickettsiae, in contrast to chlamydiae and *Wolbachia persica*, when in crude suspensions, were highly susceptible to the action of trypsin. Final suspensions were made in diluent K 36 (ref. 8), 0.1 molar potassium chloride, 0.015 molar sodium chloride, 0.05 molar potassium phosphate buffer, pH 7.0, to which was added crystalline bovine plasma albumin ('Pentex', final concentration 3 mg/ml.). Concentrated suspensions did not lose metabolic activity when maintained in these conditions at 0° C overnight or even for 2 days.

The metabolic activities of the purified suspensions were determined in 25 ml. Erlenmeyer flasks to which were added the rickettsial suspension, usually containing 0.2–1.0 mg of rickettsial protein, 2.5 × 10<sup>–3</sup> molar magnesium chloride, 5 × 10<sup>–4</sup> molar manganese chloride and substrate labelled with carbon-14 (8.3 × 10<sup>–3</sup> molar) in a total volume of 2.4 ml. The flasks were fitted with small plastic cups suspended from rubber stoppers to which were added 0.2 ml. aliquots of 1 molar 'Hyamine' to trap the carbon dioxide<sup>9</sup>. The flasks were incubated for 2 h at 32° C in a metabolic shaker and the reaction was terminated by the injection of 0.6 ml. of 25 per cent trichloroacetic acid/flask. After an additional 0.5 h of incubation, the cups were placed in liquid scintillation vials and to each were added 2.5 ml. of methanol and 15 ml. of toluene scintillant. The radioactivity of the carbon dioxide was determined in a liquid scintillation counter and the amount of carbon dioxide produced was calculated on the basis of the specific activity of the original substrate. Carbon dioxide produced in the absence of micro-organisms was subtracted. Normal yolk sac preparations, subjected to the same procedures of purification, showed negligible activity. Variation among triplicate tests with rickettsiae was usually less than 5 per cent.

For electron microscopy purified suspensions were centrifuged twice and the pellets were suspended the

first time in 0.26 molar ammonium acetate, the second time in the same solution plus formaldehyde to a final concentration of 0.37 per cent. After 48 h the suspensions were centrifuged again, the pellets were washed with distilled water and suspended in a 1 per cent aqueous solution of osmium tetroxide for 1 h. The specimens were dehydrated through several changes of 'Cellusolve' mixtures increasing from 50 per cent to the pure reagent. After being left overnight in 1:1 'Epon-Cellusolve' mixture, the specimens were embedded in 'Epon', sectioned and stained for 7 min with uranyl acetate and for 5 min with lead citrate.

The average metabolic experiment required the processing of 100 to 150 yolk sacs. Approximately 4 per cent to 25 per cent of the original infectivity was recovered in the final purified suspension or 0.05–0.1 mg of rickettsial protein for each yolk sac. One milligram of rickettsial protein corresponded to approximately  $5 \times 10^7$  chick embryo  $LD_{50}$ .

Light microscopy or electron microscopy of shadowed preparations revealed little, if any, material of host origin in the final preparation. The degree of purity could best be assessed, however, from electron micrographs of sectioned material. All the structures displayed in Fig. 1, except for a staining precipitate, appear to be of rickettsial origin. The micro-organisms are approximately  $0.5\mu$  wide and up to  $3\mu$  long. Details of structure can be recognized (Fig. 2) as previously described in *R. rickettsi* grown in tissue culture<sup>10</sup> and *R. quintana* grown *in vitro* or in the louse<sup>11</sup>.

Results of typical metabolic experiments are shown in Table 1. Of the substrates tested, glutamate was used most vigorously. Production of carbon dioxide in two experiments shown in Table 1, and other experiments not shown, varied from 0.5–1.0  $\mu$ mole/mg of rickettsial protein for the 2 h period of incubation. Glutamine and pyruvate were utilized less intensely: the ratio of carbon dioxide from glutamate to that obtained from glutamine was approximately 3:2, of glutamate to pyruvate 3:1. Approximately half of the carbon dioxide from pyruvate was derived from carbon 1, and one-quarter each from carbons 2 and 3. Two active preparations, as judged by

glutamate utilization, failed to produce carbon dioxide from glucose.

Table 2 illustrates an experiment carried out by the conventional Warburg technique, as well as the technique described here. With the collection from 230 yolk sacs and 2.4 mg of rickettsial protein/flask it was clearly shown that glutamate stimulated the oxygen consumption of *R. rickettsi*. The metabolic activity, however, was not sufficiently great for an accurate determination of the respiratory quotient.

Table 1. CARBON DIOXIDE PRODUCED BY *Rickettsia rickettsi*\*

Experiment No.	Substrate	$\mu$ moles/mg of protein	
1	Glutamate	0.54	0.60
	Glutamine	0.35	0.35
2	Glutamate	0.86	
	Pyruvate: carbon 1	0.14	
	carbon 2	0.08	
	carbon 3	0.09	

\* The micro-organisms were incubated for 2 h at 32° C. Glutamate and glutamine were randomly labelled with carbon-14; pyruvate was labelled as indicated. Data represent means of triplicate flasks. Experiment 1 was carried out with two concentrations of rickettsiae.

Table 2. GLUTAMATE METABOLISM OF *R. rickettsi*\*

No addition	Glutamate
Oxygen consumed	
0.40	1.50
Carbon dioxide produced	
Not tested	1.95

\* Data are expressed in  $\mu$ moles and represent means of triplicate flasks, each containing 2.4 mg of rickettsial protein and incubated for 2 h at 32° C.

By these metabolic tests, which agree with those of Price<sup>3</sup>, *R. rickettsi* appears to be most closely related to the typhus rickettsiae, which utilize glutamate, glutamine, and pyruvate in the same decreasing order<sup>12–15</sup>. *R. quintana*, which has an ecology similar to that of typhus rickettsiae but grown extracellularly, utilizes succinate and glutamine more vigorously than glutamate<sup>16</sup>. *Coxiella burnetii*, which is a tick symbiote like *R. rickettsi*, has a glutamate dehydrogenase<sup>17</sup>, but metabolizes pyruvate as its chief substrate<sup>18</sup>. Another tick symbiote, *Wolbachia persica*, appears to be unrelated, because in contrast to rickettsiae it respire vigorously in the presence of glucose<sup>19</sup>. In the absence of criteria such as nutritional requirements, the investigation of the metabolic activities

## BIOCHEMISTRY

### Correlation between the Concentration of Adenosine Triphosphate and the Biosynthesis of Porphyrins in the Livers of Rats Intoxicated with 'Sedormid'

THE well known spontaneous and rapid decrease in the formation of excess porphyrin in several experimental porphyrias after cessation of administration of the toxic agent seemed to us to provide a particularly interesting possibility to assess the role of adenosine triphosphate (ATP) in the quantitative regulation of the biosynthesis of porphyrins. We have observed in a long series of experiments this role of ATP *in vitro* as well as *in vivo*<sup>1</sup>.

For the present investigation, allylisopropylacetyl-carbamide ('Sedormid') porphyria of rats was chosen because there have been several reports that the formation of porphyrins returns to practically normal values in a few days after the administration of the drug has been stopped.

Four groups of female Wistar rats weighing about 200 g and fed a balanced diet were investigated. The rats of the first group served as controls. Those of the second group received by gastric intubation a daily dose of 'Sedormid' (400 mg/kg) during 6 days; they were killed on the morning of the seventh day by decapitation. The rats of the third and fourth groups were intoxicated in the same manner, but were killed 2 and 4 days, respectively, after the last dose of 'Sedormid'.

In the liver removed immediately after death, the concentration of ATP was determined by the luciferase method<sup>2</sup> and that of porphyrins, extractable by ether, by the measure of the optical density of their Soret bands. For quantitative investigations of urinary excretion of  $\delta$ -aminolevulinic acid (ALA) and uroporphobilinogen (PBG), the column chromatographic technique of Mauzerall and Granick<sup>3</sup> was used. Urinary uroporphyrin and coproporphyrin were measured following the technique devised by Rimington<sup>4</sup>.

As is shown in Table 1, we have observed in the rats of the second group a decrease in the hepatic concentration of ATP and an increase in the hepatic concentration of porphyrins as compared with the normal controls. The differences of the means are statistically highly significant.

Table 1.

	Per 100 g of liver (wet weight) ATP ( $\mu$ moles)	Free porphyrins ( $\mu$ g)
Group I (10 rats)	230 $\pm$ 9.7 ( $\pm$ S/ $\sqrt{n}$ )	6.7 $\pm$ 0.68
Group II (14 rats)	150 $\pm$ 9.1	73.0 $\pm$ 13.8
	as compared with group I	
	$t = 6.01$ $P < 0.001$	$t = 4.09$ $P < 0.001$
Group III (13 rats)	185 $\pm$ 7.9	28.0 $\pm$ 6.6
	as compared with group II	
	$t = 2.575$ $P < 0.02$	$t = 2.684$ $P < 0.02$
Group IV (11 rats)	211 $\pm$ 15.3	13.2 $\pm$ 2.7
	as compared with the normal controls (group I)	
	$t = 1.004$ $P > 0.05$	$t = 2.507$ $P < 0.05$

Group I, Normal controls; Group II, rats intoxicated by a daily dose (400 mg/kg) of 'Sedormid' during 6 days; Groups III and IV, rats intoxicated in the same manner, but killed 2 and 4 days, respectively, after the last dose of 'Sedormid'.

In the rats of groups III and IV, in which the administration of 'Sedormid' was stopped 2 and 4 days, respectively, before death, a progressive increase of the hepatic concentration of ATP and a progressive decrease in the concentration of porphyrins were observed as compared with the animals of the second group. In the rats of the fourth group, mean values were quite near to the normal means (Table 1).

Comparison of the hepatic concentration of ATP and of porphyrins in the rats of each group intoxicated by 'Sedormid' shows a statistically significant negative correlation. Thus for group II,  $r = -0.644$  ( $P < 0.02$ ), for group III  $r = -0.598$  ( $P < 0.05$ ) and for group IV,  $r = -0.629$  ( $P < 0.02$ ). (The correlation coefficient  $r$  was calculated from the formula

$$r = \frac{\sum d \cdot d_1}{\sqrt{\sum d^2 \cdot \sum d_1^2}}$$

where  $d$  is the difference between the individual concentration of ATP and the mean for the group and  $d_1$  a similar term for the concentration of porphyrins.)

We observed, in common with others, that the urinary excretion of ALA, PBG, uroporphyrin and coproporphyrin was much raised during the administration of 'Sedormid', but became practically normal about 4 days after the administration was stopped.

The findings reported here show, even more clearly than our earlier observations, a role of ATP in the quantitative regulation of porphyrin biosynthesis. The inverse correlation between the hepatic concentration of ATP and that of porphyrins affords a statistically significant negative correlation between these two concentrations, not only during the production of 'Sedormid' porphyria but also during its spontaneous improvement after withdrawal of the drug. It could be objected that the variations in the hepatic concentrations of ATP and porphyrins might depend on a third unrecognized factor. Militating against this possibility are our earlier observations showing the prevention of 'Sedormid' porphyria (and the other experimental porphyrias) by daily administration of ATP or its precursors such as AMP and inosine<sup>5,6</sup>.

### Possible Mechanisms for the Enzymatic Condensation of Porphobilinogen

THE problem of the mechanism of the enzymatic condensation of four moles of porphobilinogen (PBG) to form uroporphyrinogen III (urogen III) remains unsolved. Bogorad<sup>1-3</sup> has been able to direct the course of this condensation *in vitro* by using one or two enzyme systems. Porphobilinogen deaminase (PBG-D) or uroporphyrin I synthetase from spinach catalyses the formation of uroporphyrin I (urogen I) from porphobilinogen. Uroporphyrinogen isomerase (U-Is) or uroporphyrinogen III co-synthetase from wheat germ and PBG-D direct the formation of urogen III from porphobilinogen. Kinetic investigations carried out by Bogorad suggest that the action of PBG-D on porphobilinogen is rate-determining and that uroporphyrinogen isomerase participates in a faster step for which porphobilinogen is also a substrate. Uroporphyrinogen isomerase does not act on porphobilinogen alone nor on urogen I (ref. 4). This suggests that some

intermediate, the synthesis of which is catalysed by PBG-D, and porphobilinogen are substrates for uroporphyrinogen isomerase.

Of the mechanisms proposed, those amenable to testing have been eliminated. Evidence has been presented against (a) a loss of or exchange of free formaldehyde<sup>4</sup>, and (b) the participation of opsopyrrole dicarboxylic acid<sup>5-8</sup>, porphobilinogen- $\alpha$ -carboxylic acid, cryptopyrrole-dicarboxylic acid, hemopyrrole dicarboxylic acid, porphobilinogen lactam<sup>9</sup>, isoporphobilinogen<sup>10</sup> and the dipyrromethanes, I, II and III (refs. 8 and 10), in purified systems which catalyse the conversion of porphobilinogen to urogen III with one or more enzymes.

A possible mechanism which needs to be explored is the initial formation of a linear tripyrrole which is catalysed by PBG-D which serves as a substrate for uroporphyrinogen isomerase along with a fourth mole of porphobilinogen. Bogorad<sup>2,9</sup> has detected an Ehrlich-reacting pyrrole intermediate from the reaction of PBG with PBG-D in the presence of hydroxylamine. Uroporphyrinogen isomerase could then direct condensation of PBG on to the substituted  $\alpha$ -carbon of ring C. Intramolecular rearrangement of a one-carbon unit should give a linear tetrapyrrole which would yield urogen III exclusively. Bullock, Johnson, Markham and Shaw<sup>11</sup> have suggested a plausible mechanism for such a rearrangement.

In the absence of the directing influence of uroporphyrinogen isomerase, head to tail condensation would lead to urogen I only.

Porra's work on *Clostridia*<sup>12</sup> indicates that urogen III is probably the precursor for the corrin nucleus.

An alternative suggestion which is worth testing and is somewhat analogous to Bogorad's<sup>9</sup> dipyrromethane proposal is the condensation of PBG with a linear tripyrromethane at ring 2 with the release of  $\alpha$ -aminomethyl-PBG or similarly substituted PBG which then reacts to yield a linear tetrapyrrole precursor for urogen III.

### DNA during the Development of the American Sea Urchin

We reported recently on the properties of the deoxyribonucleic acids isolated from the egg, sperm and adult diploid tissues of the American sea urchin *Arbacia punctulata*<sup>1</sup>. It was found that the DNA isolated from the two haploid cells had similar buoyant densities of 1.700 g/cm<sup>3</sup>. This can be taken to mean that the DNAs from these sources have identical base compositions<sup>2</sup>. On the other hand, the DNA derived from adult diploid cells exhibited a buoyant density of 1.702 g/cm<sup>3</sup>. If this difference in the density values of the haploid and adult

diploid cells reflects a real shift in base composition, it is indeed a most unexpected finding. The current ideas concerning cellular development and differentiation are based on the belief that just as the adult diploid cells derive from the original zygote by orderly mitotic division, so the DNA from the adult cell is derived from the fertilized egg by exact replicative cycles. Because the DNAs of sperm and egg have identical base compositions, this belief would lead to the prediction that a diploid cell resulting from this union would contain DNA with a correspondingly identical base composition. Implied in this concept is the hypothesis that cellular differentiation is not the result of changes in the DNA but rather that it is controlled by histone-masking and/or "cytoplasmic regulators" which have now been equated with messenger RNA.

In view of the observation that adult diploid cells seemed to possess a base composition not identical with that of the two gametes, the present investigation was undertaken to study the DNA isolated at various stages of embryonic development.

Table 1. BUOYANT DENSITIES OF DNAs ISOLATED AT VARIOUS STAGES OF DEVELOPMENT OF *Arbacia punctulata*

Specimen	Density (g/cm <sup>3</sup> )*	Footnote
Sperm	1.700	a
Egg	1.700	a
Adult diploid	1.702	a
Fertilized egg (pre-cleavage)	1.700	b
2-cell stage	1.700	b
16-cell stage	1.700	b
Morula	1.700	b
Blastula	1.701	c
Gastrula	1.702	d
Pluteus	1.702	c

\* Portions of the echinoderm DNA together with a reference sample (*Micrococcus lysodeikticus* DNA, 1.731 g/cm<sup>3</sup>) were placed in a caesium chloride solution, density 1.70 g/cm<sup>3</sup>, and centrifuged in the 'Spinco' Model E analytical ultracentrifuge at 44,770 r.p.m. for 24 h. The bands formed by these nucleic acids at their buoyant equilibrium positions were photographed with the ultra-violet optical system. The buoyant densities of the samples were calculated from tracings of the photographs obtained with a 'Joyce-Loebl Mark III' microdensitometer.

a. Data taken from a previous study<sup>1</sup>.

b. Two specimens were prepared by a procedure using hot phenol<sup>17</sup>. Each sample was analysed twice.

c. Two specimens were prepared by a procedure using detergents<sup>18</sup>. Each sample was analysed twice.

d. One sample was prepared by the phenol procedure and two of the samples were prepared by the procedure using detergent. Each specimen was analysed twice.

The data summarized in Table 1 indicate that the DNAs isolated from the embryo between the time of fertilization and the beginning of the blastula stage have densities identical with those of DNAs isolated from haploid cells. The DNA isolated during the late blastula stage exhibits a slightly increased buoyant density while DNA isolated after this stage has an even greater density, identical with that of adult diploid tissue.

The data presented here would indicate that the replication of DNA is not exact, which is contrary to Watson and Crick's fundamental theory. If this should be the case, an active role for DNA in cellular differentiation might have to be postulated. (The presence of an excess of cytoplasmic DNA in the unfertilized sea urchin egg is known. The role of this nucleic acid in the phenomenon described here, however, may not have to be taken into consideration, as it has been shown to have a buoyant density identical with that of the nuclear DNA<sup>1,3</sup>.)

In searching for a mechanism that could explain this unexpected finding, the report of Gross *et al.*<sup>4</sup> on the role of messenger RNA synthesis in embryonic development might be germane. Gross and his collaborators found that in the presence of actinomycin D, the development of *Arbacia punctulata* could proceed to the blastula stage but no further. Presumably, continued differentiation was dependent on the availability of new messenger RNA. Because blastulation is also the stage at which a change in the density of the DNA is first noticed, it is possible that messenger RNA might control synthesis of

DNA. Recent work with the RNA-containing Rous sarcoma virus indicates that RNA may indeed transfer information to DNA (ref. 5).

Mention should also be made of the study of Comb<sup>6</sup>, who found that the DNA of the developing sea urchin embryo did not become methylated until the gastrula stage. Although it is unlikely that the extent of methylation would affect significantly the buoyant density of DNA, its contributory effect cannot be ruled out completely.

Actually, evidence of a system somewhat more complicated than an ordered duplication of DNA during successive mitosis can be obtained from recently published studies on the banding properties of DNAs from various animal sources in gradients of caesium chloride. For example, the presence of satellite bands in DNA preparations is well documented<sup>7</sup>. In some cases these bands appear late in the developmental cycle and could not, therefore, have arisen by orderly replication of a gamete in which this special DNA could not be detected<sup>8</sup>. Differences in the buoyant densities of the DNAs of gametes and of somatic cells have been found not only for *Arbacia punctulata* but for the South African "clawed toad" *Xenopus laevis*<sup>9</sup>, the squid *Loligo pealii*, the clam *Spisula solidissima*, and the American oyster *Crassostrea virginica*<sup>10</sup>.

It is also noteworthy in this respect that Mazia and Plaut<sup>11</sup> obtained autoradiographic evidence that the distribution of DNA in the daughter chromosomes of *Crepis* is unequal.

If the DNA of the sea urchin actually "differentiates" during the late blastula stage, a number of biological phenomena become explicable. Spemann<sup>12</sup> and Seidel<sup>13</sup> reported that nuclei isolated from cells during early development are "equipotential" in directing early development. Briggs and King<sup>14</sup> studied this phenomenon further using greatly refined techniques. Their investigations revealed that nuclei taken from late gastrulae are no longer equipotential in directing the development of enucleated eggs. It is perhaps no coincidence that this is the stage when the maximum change in the buoyant density of the DNA is first apparent, although it should be pointed out that the studies dealing with nuclei transplantation were not performed with *Arbacia punctulata*.

Cross-fertilization between certain echinoderms has been reported (for example, *Paracentrotus* × *Arbacia*)<sup>15</sup>. These combinations cleave normally at first, but gastrulation is a fatal event. It is known that the deoxyribonucleic acids derived from the sperm of a number of echinoderms possess identical or very similar base compositions<sup>1,3,16</sup> and it is possible that they even possess some sequence homologies, thus permitting orderly mitosis and DNA duplication to proceed to the completion of blastulation. When gastrulation is about to begin and the specific potentialities of these nucleic acids are expressed in a non-orderly replication, however, this process is either prevented or the new DNA (or the product whose synthesis it directs) is not compatible with survival of the hybrid.

The speculation offered in this paper is based on data obtained mainly from one biological system; however, preliminary results with other species (*Loligo pealii*, *Spisula solidissima*, *Crassostrea virginica*<sup>10</sup>) are in accord with it. If the experimental findings are confirmed, a re-examination of the role of DNA in cellular differentiation may be warranted.

Current studies that are being made of the isotopic distribution of DNA during the different embryonic stages may help to elucidate the mechanism directing the "un-ordered" replication.

This study was supported by a contract between the Office of Naval Research, U.S. Department of the Navy, and Columbia University, and by a grant from the U.S. Public Health Service from the National Cancer Institute.

We thank Mr. S. Rosenkranz for performing the centrifugal analyses.

## Nuclear RNA Synthesis in Human Leukaemic Cells

SEVERAL investigators<sup>1-4</sup> have demonstrated RNA synthesis in normal and leukaemic lymphocytes by extraction of RNA from intact cells. To gather more information about RNA synthesis in human leukaemic leukocytes, experiments were designed to characterize nuclear RNA sedimentation patterns. Particular emphasis was placed on the comparison of nuclear RNA synthesis in cells derived from patients with chronic granulocytic leukaemia to those from patients with chronic lymphocytic leukaemia. These leukaemic cell types were chosen for investigation as examples of readily accessible human neoplastic cells of relatively low grade malignancy which appear to originate from two distinct haematopoietic cell lines.

Heparinized whole blood drawn from patients was allowed to sediment for 30-45 min at room temperature; the leukocyte-containing plasma layer was withdrawn, and glucose (3 mg/ml.) and sodium bicarbonate (1 mg/ml.) were added. Aliquots containing approximately  $9 \times 10^8$  cells were incubated at 37° C after addition of uridine-<sup>3</sup>H, to give a final concentration of 1  $\mu$ Ci/ml. (specific activity 3,620 c./mole). Nuclei prepared with citric acid<sup>5</sup> were intact and of high purity as determined by light microscopy. Nuclear RNA was isolated by the method of Salzman *et al.*<sup>6</sup>. In all nuclear RNA extraction procedures, the sodium dodecyl sulphate concentration was 0.34 per cent, and the phenol was freshly redistilled.

The pattern of nuclear RNA synthesis in chronic granulocytic leukaemia cells during 360 min of incubation (Fig. 1) indicated early appearance of an 8S peak, persisting throughout the 90 min of incubation. At 90 min, a 4S peak emerged and the radioactivity was distributed to label a heterogeneous spectrum of RNA. After 90 min of incubation, the 8S peak disappeared, whereas the 4S peak persisted throughout 360 min of incubation. By

180 min, there was labelling in the ribosomal regions, and by 360 min the radioactivity curve approximated the optical density curve. The 8S peak appeared to be an unstable intermediate in nuclear RNA synthesis. Ribosomal RNA was synthesized after the 4S and the polydisperse 16S regions had been labelled.

Table 1. SPECIFIC ACTIVITY (C.P.M./O.D.) OF RNA PEAKS LABELLED AT 6 H

	4S	Peaks	18S	28S
Chronic lymphocytic leukaemia				
Experiment 1	4,150	1,050	1,140	
Experiment 2	4,450	4,000	2,500	
Average	4,300	2,525	1,820	
Chronic granulocytic leukaemia				
Experiment 1	14,800	7,050	4,750	
Experiment 2	6,000	2,560	2,700	
Average	10,400	4,805	3,725	

The pattern of nuclear RNA synthesis in chronic lymphocytic leukaemia cells appeared to be distinctly different from chronic lymphocytic leukaemia. A small rapidly labelled 4S peak appeared which remained throughout the 6 h incubation (Fig. 2). An intermediate (24–26S) peak also formed rapidly and persisted for 90 min, at the end of which some high molecular weight RNA (36S) was also present. After 30 min of incubation, there was progressive formation of ribosomal RNA as well as persistence of higher molecular weight RNA. The rapidly labelled 8S RNA component was not observed in chronic lymphocytic leukaemia nuclei. Quantitation of specific activity in the RNA peaks isolated from the same cells varied considerably in separate experiments (Table 1). When actinomycin D (10  $\mu$ g/ml.) was added after 30 min of incubation, uridine- $^3$ H incorporation into RNA ceased in both chronic lymphocytic and chronic granulocytic leukaemia nuclei. The number of counts in each peak decreased although the pattern of labelling established by

Fig. 1. Nuclear RNA synthesis in chronic granulocytic leukaemia cells. The differential cell count was 50 per cent polymorphonuclear leukocytes, 16 per cent stabs, 8 per cent metamyelocytes, 6 per cent basophils, and 6 per cent monocytes. Leukaemic granulocytes were incubated with uridine- $^3$ H and nuclear RNA was extracted at intervals. Alcohol-precipitable RNA was dissolved in 1 ml. of 0.01 molar acetate buffer (pH 5.1) containing 0.1 molar sodium chloride and 0.001 molar magnesium chloride and layered on to a 5 per cent to 20 per cent sucrose gradient in acetate buffer (magnesium chloride omitted). These gradients were centrifuged at 25,000 r.p.m. for 12 h in a Spinco 'SW-25' rotor. The tube was then punctured and fractions were collected for determinations of optical density at 260 m $\mu$  in a Beckman spectrophotometer. Radioactivity in these fractions was determined by adding Bray's solution and counting in a Beckman liquid scintillation spectrometer.

Fig. 2. Nuclear RNA synthesis in chronic lymphocytic leukaemia cells. The differential cell count was 99 per cent abnormal lymphocytes, and 1 per cent polymorphonuclear leukocytes. Procedures are similar to those in Fig. 1.

30 min remained unchanged without progression of label into ribosomal RNA.

These results are not directly comparable with those reported by other investigators<sup>1-4</sup>, because our work involved the synthesis of nuclear RNA rather than total RNA. Granted that other differences exist in the methods of RNA extraction, these results of early labelling of 4S RNA from chronic lymphocytic leukaemia cells are compatible with data reported by Silber *et al.*<sup>1</sup>. The present data, however, differ from their finding of lack of incorporation of radioactivity into the 16S and 28S peaks after 180 min in both chronic lymphocytic leukaemia and chronic granulocytic leukaemia cells.

Rubin and Cooper<sup>4</sup> investigated the sedimentation patterns of total RNA extracted from intact normal resting lymphocytes as well as from lymphocytes stimulated with phytohaemagglutinin (PHA). Lymphocytes stimulated with PHA undergo progressive blastic transformation<sup>8</sup>, and so it is of interest to compare the RNA sedimentation patterns with the RNA patterns of leukaemic leukocytes. After a 6 h exposure to uridine, the sedimentation patterns of total RNA from normal lymphocytes resemble that of mammalian cellular RNA<sup>9</sup>, with the largest amount of label found in the 4S region and smaller amounts in the 18S and 28S peaks<sup>4</sup>. From a comparison of the sedimentation patterns of total RNA extracted from normal lymphocytes and lymphocytes stimulated with PHA with the sedimentation patterns obtained with *n*-RNA from CLL lymphocytes, we made several observations. First, there is a striking similarity in optical density characteristics (28S, 18S, and 4S peaks). Second, the pattern of incorporation in chronic lymphocytic leukaemia *n*-RNA resembles that of the resting lymphocyte more than it does the lymphocyte stimulated by PHA in the synthesis of small quantities of 4S at 30 min followed by progressive but low levels of ribosomal RNA formation. By contrast, the lymphocyte stimulated by PHA incorporated much larger quantities of uridine into all fractions and particularly into polydisperse high molecular weight RNA. Finally, pulse-chase with actinomycin D resulted in loss of the majority of extractable

RNA counts from leukaemic nuclei as with normal and PHA-stimulated lymphocytes. This suggests the presence of large proportions of rapidly labelled RNAs which are unstable, because loss of optical density did not occur on exposure to actinomycin D. In this respect, the lymphocytes appear to differ from the nuclear RNA of HeLa cells, in which 70 per cent of the rapidly labelled RNA is stable<sup>6</sup>. Cooper and Rubin<sup>10</sup>, however, have recently shown that the pattern of labelling of normal lymphocytes can be varied by changing the conditions of incubation.

The rapidly labelled 8S peak from chronic granulocytic leukaemia nuclei was not found in chronic lymphocytic leukaemia nuclei. It is either a ribosomal precursor or messenger RNA. The instability of this fraction would be consistent with both possibilities; the absence of formation of ribosomal RNA following actinomycin D added after 30 min does not provide proof of either. Definition of this peak will depend on characterization of a messenger fraction in leukaemic nuclei in a manner similar to that accomplished in rat liver cells<sup>11-13</sup>, and ultimate identification must depend on stimulation of specific proteins.

Although the results obtained with *n*-RNA may not agree completely with results obtained with RNA extracted from intact cells, it is extremely difficult, with present methods, to extract total undegraded RNA from intact cells, and in particular from intact chronic lymphocytic leukaemia leukocytes. It has been our experience that RNA is extracted with greater ease from leukaemic nuclei because most of the RNase is removed. Nevertheless, there remains considerable variation in the completeness of RNA extraction between duplicate experiments (Table 1). The extent of this methodological variability has not been discussed in other work on leukaemic cells, making quantitative comparisons difficult.

## Synthesis of RNA in Isolated Cells from *Xenopus laevis* Embryos

INVESTIGATIONS with amphibian embryos are of particular interest because of the recent finding that a sequential synthesis of RNA species takes place during early development: the first, synthesized during very early stages, is soluble RNA, followed by ribosomal RNA, the synthesis of which predominates later<sup>1,2</sup>. These sequential events may provide a parameter of cellular differentiation. The embryo has, however, a definite disadvantage: it needs few exogenous substances except for several inorganic ions which it requires until the feeding stage. For nucleic acid and protein synthesis carbon dioxide is perhaps the

only available precursor which can be incorporated freely into the embryo<sup>3</sup>. We have found that the cells obtained from dissociated embryo actively incorporate a number of radioactive precursors when these are added to the medium and synthesize RNA species sequentially as do whole embryos.

Embryos of *Xenopus laevis* were obtained<sup>1</sup> and kept at 18° C–20° C in the presence of penicillin and streptomycin. Glasses and media used were all sterilized and care was taken to avoid bacterial contamination. Jelly was removed by treatment with 2.5 per cent thioglycollate; dissociation and culture were carried out as previously described<sup>4</sup>.

The cells from 250 dissociated blastulae (stage 8)<sup>5</sup> were incubated in the medium containing 0.25 µc./ml. of uracil labelled with carbon-14 for 10 h and the cells equivalent to fifty embryos were sampled at 2 h intervals for measurements of incorporation into acid-insoluble material. At the same time, 250 sibling embryos were labelled and measured. (When cells were labelled with tritiated-uridine, tritiated-thymidine and protein hydrolysate labelled with carbon-14, it was easy to measure the incorporation of the cells obtained from less than five embryos.) During this period, the blastulae reached stage 14–15. Fig. 1 illustrates the results obtained. The incorporation into the cells rises very sharply throughout the incubation. At the end of the 10 h incubation, the incorporation is more than fourteen times that into the whole embryos. The differences in incorporation between cells and embryos increased with the age of the embryos used, for embryos gradually lost their permeability. After being labelled for 10 h with 3.3 µc./ml. of tritiated-uridine, the cells were collected and RNA was extracted with phenol and detergent-bentonite<sup>2</sup> for methylated albumin column chromatography<sup>6</sup>. The pattern showed all characteristics of that obtained with the whole embryos used as controls; that is, soluble RNA was highly radioactive and the radioactivity peak of ribosomal RNA was low. That ribosomal RNA was eluted as a single peak is of great importance. Ribosomal RNA of bacterial origin is eluted in two peaks while ribosomal RNA from embryos of *Xenopus* and *Rana*<sup>2</sup> shows only a single peak. It is, then, certain from the chromatogram that the synthesized RNA was of embryonic origin. Actinomycin D (0.5 µg./ml.) reduced the incorporation of tritiated-uridine by 83 per cent. Also tritiated-thymidine and protein hydrolysate labelled with carbon-14 incorporated

Fig. 1. Incorporation of uracil labelled with carbon-14 into acid-insoluble material of the cells obtained from dissociated blastulae and that of the sibling whole blastulae. The ordinate is c.p.m./fifty embryos or isolated cells equivalent to fifty embryos. ○, Isolated cells; ●, whole embryos.

into acid-insoluble fraction of the cells at constant rates during a 10 h labelling period. Electron microscopic observations revealed that after culture for 10 h the isolated cells retained their normal features; furthermore, nucleoli appeared during this period.

The cells obtained from embryos dissociated at the blastula stage continued to take up tritiated uridine for 25 h. After a 20 h culture, during which the medium was changed three times, the cells were given 2  $\mu$ Ci/ml. of tritiated uridine for 5 h. RNA was purified with phenol, detergent and bentonite and chromatographed on a column of methylated albumin. It was shown that the cells were intensely synthesizing ribosomal RNA as well as soluble RNA. The whole embryos obtained from the same batch were given simultaneously labelled carbon dioxide for 5 h. The pattern which was obtained was essentially the same as that of the dissociated embryonic cells. Again, the elution pattern of ribosomal RNA was a single peak in both cases.

These experiments have demonstrated that the dissociated embryonic cells continued to incorporate a variety of radioactive precursors for a relatively long period and were synthesizing first soluble RNA and then ribosomal RNA in addition. It seems that these isolated cells, instead of whole embryos, can be used to investigate differentiation.

### Amino-acid Composition of $\alpha_{s1}$ -Casein D

The genetic polymorphism of  $\alpha_s$ -casein was first demonstrated by Thompson *et al.*<sup>1</sup> using the technique of starch-gel electrophoresis. Since that time three genetically controlled variants have been found, which have been denominated as  $\alpha_{s1}$ -casein A, B and C in order of their decreasing electrophoretic mobility.

The amino-acid compositions of these variants have been reported recently<sup>2,3</sup>. The variants B and C of  $\alpha_{s1}$ -casein appeared to differ only by one residue in the amino-acid composition:  $\alpha_{s1}$ -casein B had one more glutamic acid, whereas  $\alpha_{s1}$ -casein C contained one more glycine. The differences found by Gordon *et al.*<sup>3</sup> between  $\alpha_{s1}$ -casein A and B were manifold, and suggest that the former variant cannot be considered as a mutant of  $\alpha_{s1}$ -casein B. More recently Grosclaude<sup>4</sup> reported the discovery of a fourth genetically controlled  $\alpha_{s1}$ -casein, isolated from the milk from one cow of the Flemish breed. According to the recommendations given for the nomenclature of milk proteins<sup>5</sup> it was designated as  $\alpha_{s1}$ -casein D.

The present paper describes the amino-acid composition of  $\alpha_{s1}$ -casein D and compares it with those of the  $\alpha_{s1}$ -caseins A, B and C published earlier<sup>2,3</sup>. A crude sample of  $\alpha_{s1}$ -casein D was obtained from Dr. J. Garnier, Institut National de la Recherche Agronomique, Jouy-en-Josas, France. To demonstrate the differences in electrophoretic mobility, a starch-gel electropherogram of this sample and three samples of whole casein containing the genetic variants of  $\alpha_{s1}$ -casein A, B and C, was made by the method of Wake and Baldwin<sup>6</sup>, using a tray of 50 cm length. Purification of the  $\alpha_{s1}$ -casein D sample was carried out by

column-electrophoresis, as described by Schmidt and Payens<sup>7</sup>. The amino-acid analysis was carried out using a 'Technicon' amino acid analyser as described previously<sup>2</sup>. Determination of the N-terminal group was performed by the dinitrofluorobenzene method of Sanger as described by Fraenkel-Conrat<sup>8</sup>. Identification of the N-terminal amino-acids was effected on thin layers of silica gel by the method of Brenner *et al.*<sup>9</sup>. The identification of dinitrophenyl-arginine was carried out by using high-voltage electrophoresis on thin layers of cellulose in 1 normal ammonia. During electrophoresis a voltage of 1,500 V was applied to the thin layer strip of 20 cm  $\times$  20 cm for about 30 min. The phosphorus content was determined by the method of Griswold *et al.*<sup>10</sup>. Fingerprinting of the tryptic digests of the genetic variants was carried out as described previously<sup>2</sup>.

The starch-gel electropherogram of whole casein samples which contained the genetic variants of  $\alpha_{s1}$ -casein A, B and C, together with a sample of crude  $\alpha_{s1}$ -casein D, is given in Fig. 1. From this pattern it is observed that the mobility of the new genetic variant  $\alpha_{s1}$ -casein D is intermediate between those of  $\alpha_{s1}$ -B and  $\alpha_{s1}$ -A. The relative mobility of  $\alpha_{s1}$ -casein D, calculated according to Wake and Baldwin<sup>6</sup>, is 1.13.

The results of the amino-acid analyses are given in Table 1. It is clear that the calculation of the absolute numbers of residues depends on the molecular weights chosen. Because the exact value of the molecular weight of all the different genetic variants is not yet known, we have based our calculations on a value of 28,600 which was calculated by Gordon *et al.*<sup>3</sup> from the amino-acid composition of  $\alpha_{s1}$ -casein B and C.

Considering the amino-acid composition of  $\alpha_{s1}$ -casein D as a whole, it is obvious that the amino-acid composition of the genetic variants of  $\alpha_{s1}$ -casein D and B fully agree, except for two amino-acids. Compared with  $\alpha_{s1}$ -casein B,  $\alpha_{s1}$ -casein D contains one more residue of proline and one less residue of serine. According to Pelc<sup>11</sup> such mutations are in agreement with a single base substitution in the

Fig. 1. Starch-gel electropherogram of the genetic variants of  $\alpha_{s1}$ -casein. Only the region containing the  $\alpha_{s1}$ - and  $\beta$ -caseins is shown.

messenger RNA sequence involving the coding triplets CCA/UCA. The differences between these amino-acids, however, do not explain the higher electrophoretic mobility of  $\alpha_{s1}$ -casein D. Separate determination of the number of amide groups by the method of Stegemann<sup>12</sup> showed an equal value of thirty-one residues in both cases. A difference in the electric charge of the molecule caused by the presence of different numbers of phosphate groups is unlikely, because in  $\alpha_{s1}$ -casein B and D the phosphorus contents appeared to be identical. It is therefore clear that the differences in electrophoretic mobility cannot be explained electrostatically. The N-terminal amino-acid of  $\alpha_{s1}$ -casein D was shown to be arginine, which was also found in the other genetic variants<sup>14</sup>. Fingerprints of the tryptic digests of  $\alpha_{s1}$ -casein B and D showed identical peptide patterns, which present a further indication that these proteins closely resemble each other.

On account of these results it is apparent that  $\alpha_{s1}$ -casein D is to be considered as a mutant of  $\alpha_{s1}$ -casein B. The total number of electric charges in both  $\alpha_{s1}$ -casein D and B is the same, so that the observed differences in electrophoretic mobility may be explained by the different conformations of the genetic variants. This may possibly be the consequence of the excess proline residue in  $\alpha_{s1}$ -casein D.

We thank Dr. J. Garnier for supplying a sample of  $\alpha_{s1}$ -casein D. Also we thank Mr. A. Kok and the Misses P. Both and A. C. J. Heerdt for their skilful technical assistance.

## Effect of Acetylation on the Biological Activity of Pregnant Mare Serum Gonadotrophin

DURING our recent investigation into the mechanism of action of pregnant mare serum gonadotrophin (PMS)<sup>1</sup>, we prepared a sample of highly radioactive peptide hormone. Radioactive steroid hormones are relatively easy to prepare and have been utilized in investigations on the mechanism of action of these hormones<sup>2</sup>. More recently, radioactive peptide hormones have been reported<sup>3-5</sup> to have similar biological and antigenic properties to the native proteins. Acetylation of bovine growth hormone, utilizing tritiated acetic anhydride, resulted in a sample of hormone biologically and antigenically equivalent to the native hormone<sup>6</sup>, while treatment of ACTH under similar conditions led to a loss of hormonal activity<sup>7</sup>. The results of our attempts to acetylate PMS are now reported.

PMS ('Equinex', Ayerst Laboratories) was acetylated as outlined previously for bovine growth hormone<sup>4</sup>, with slight modification. Each 5,000 IU sample of hormone was suspended in 1.0 ml. of saturated sodium acetate and the pH adjusted to 7.5 by the addition of 0.1 N sodium hydroxide, after the addition of 20  $\mu$ moles of tritiated acetic anhydride. The acetylated hormone was separated from the free acetate by passing the mixture through a 1.4  $\times$  50 cm 'Sephadex G-10' column and eluting the hormone with water. The effluent was collected in 1.5 ml. fractions. Radioactivity in these fractions was measured in a Packard scintillation counter and the hormone detected by its absorption at 280 m $\mu$ . A sample of hormone was carried through the entire procedure without adding the acetic anhydride. Evidence that the hormone had been acetylated was obtained by rechromatography of the labelled hormone and by acid precipitation.

Assay of all PMS samples was carried out by a modification of the previously published uptake investigations for phosphorus-32 (ref. 1). The PMS was administered as a single subcutaneous injection to white Leghorn cockerel chicks 24 h old. Inorganic phosphorus-32 (2.0  $\mu$ Ci/animal) was administered subcutaneously 1 h later. Distilled water served as the diluent for both materials and the total injection volume was 0.2 ml. for each. Chicks were killed by cervical fracture 24 h after hormone treatment, the testes quickly removed and weighed to the nearest 0.1 mg on a 50 mg torsion balance. Radioactivity measurements of whole testes were made on a Nuclear-Chicago gas flow counting system. Total tissue counts divided by gross weight yielded the c.p.m./mg data, which were submitted to analysis of variance.

The results of the purification of the acetylated hormone on 'Sephadex' are presented in Fig. 1. It is evident that the radioactivity completely paralleled the optical density in both chromatograms. This was good evidence that a successful acetylation of the hormone had been carried out. Further proof of this fact was obtained after acid precipitation of the hormone in the presence of carrier serum albumin. It was found that 74 per cent of the radioactivity was insoluble in 5 per cent trichloroacetic acid and the radioactivity remained bound to the protein during repeated acid precipitations.

The results of the biological assays are presented in Table 1. It is evident that acetylation of PMS hormone (PMS-A) abolished its biological activity. This loss in activity was not due to the protein being subjected to treatment with saturated sodium acetate at pH 7.5 to 8.0, as indicated by the results of the assay for the hormone sample PMS-A control.

Until the identity of the acetylated groups in the hormone is known, no reasonable speculation can be offered to explain the lack of activity that resulted. This investigation of acetylated groups may well give some indication of the important functional groups in the PMS molecule. However, acetylation cannot be used to obtain biologically active radioactive hormone. If radioactive

### Suppressing Effects of Histamine on Lipid Synthesis in Chick Aortic Cells

Most investigations of histamine activity relative to the cardiovascular system have been concerned with haemodynamic effects. In a search for the effects of various agents on lipid synthesis in aortic cells in culture it was found that histamine interferes with lipid synthesis. Furthermore, such suppression of lipid synthesis can be prevented by the addition of an antihistamine.

Aortic cells were prepared by trypsinization from the stripped aortic intimal layer of 3 week old Rhode Island Red chicks as reported previously<sup>1</sup>. The cells were suspended 1 : 300 v/v in Eagles minimum essential medium

(MEM), plus 10 per cent foetal calf serum, planted 5 ml. in each flask and cultured until monolayer sheets formed. Secondary cell lines were prepared from the primary cells by trypsinization and comparison of metabolic rates in both generations were carried out. After 4 or 5 days of culture, histamine was added for 3 days in doses of from 0.1  $\mu$ g to 10  $\mu$ g/ml. of MEM with 5 per cent calf serum. After treatment with histamine, the aortic cells were incubated with new media containing sodium acetate labelled with carbon-14 (0.44  $\mu$ Ci/ml. of MEM) for 6 h. The exposed cells were washed three times and trypsinized. The cellular lipids were extracted twice with methanol and chloroform (1 : 2 v/v)<sup>2</sup> and washed repeatedly until the washed aqueous portion was no longer radioactive. Half of the washed lipid fraction was measured gravimetrically for total lipids after concentration and drying under a nitrogen stream. The other half was dissolved in acetone and ether (1 : 2 v/v); free sterol was precipitated as digitonide and purified by the Sperry and Webb method<sup>3</sup>. Free sterol was determined by the acetic acid-ferrous sulphate reagent<sup>4</sup>.

Preliminary experiments had shown that the amount of labelled acetate incorporated into lipids is adequate at 6 h and continues in a linear fashion for at least 12 h. The presence of histamine in the aortic cells for 3 days demonstrated its inhibitory effects on lipid synthesis in various conditions: in both primary and secondary cells; and in cells cultured in MEM with or without human lipaemic serum (total lipids 790 mg per cent and cholesterol 318 mg per cent). Examinations of the cell cultures for deleterious effects of histamine were negative. The cell monolayers were intact after 3 days of exposure to the highest

Fig. 1. Effect of the concentration of histamine on incorporation of labelled acetate into total lipids (solid line) and free sterol (broken line) in primary aortic cells. The cells were incubated with histamine at the concentration indicated for 3 days. The points and vertical lines indicate the means and standard errors. The differences in the specific activities of synthesized lipids between each level of the concentrations and of the corresponding controls are compared for statistical analysis. \*  $P < 0.01$ . \*\*  $P > 0.001$ .

concentration; cell counts and lipid weights were equivalent to control values.

Fig. 1 illustrates the effect of the quantity of histamine on lipid synthesis in the primary aortic cells. At the concentration of 0.1–10  $\mu\text{g}/\text{ml}$ . of MEM, incorporation of labelled acetate into total lipids and free sterol were significantly suppressed by histamine. The highest specific activity in the free sterol portion was related to a greater suppression of incorporation of carbon-14.

The effect of the incubation time is shown in Fig. 2, where both primary and secondary cells were incubated for the time indicated with histamine in a dose of 0.1  $\mu\text{g}$  or 1  $\mu\text{g}/\text{ml}$ . of MEM. Both generations showed similar results and the data are combined in the figure. Again, the suppression of lipid synthesis by histamine is found to be related to the incubation time and dose in both generations. In the two concentrations the rates of suppression were significant when compared with the zero levels.

The data given above clearly indicate that histamine possesses inhibitory properties toward lipid synthesis. Furthermore, the antagonistic effect of an antihistamine, diphenhydramine hydrochloride (DPH), confirmed the above observation. When this compound was added with histamine for 3 days in the primary cells, the suppression of lipid synthesis by histamine was prevented (Fig. 3). The greater concentration of DPH showed incorporation of labelled acetate in total lipids and free sterol, equivalent to the untreated control value. It

Fig. 2. Effect of the incubation time of histamine on free sterol synthesis in aortic cells. Histamine was added in a dose of 0.1  $\mu\text{g}/\text{ml}$ . of MEM (solid line) and 1  $\mu\text{g}/\text{ml}$ . of MEM (broken line) at the time indicated. Each determination was made using four to six samples. Statistical comparison of the synthesized sterol was made between the zero time and the indicated incubation time and symbolized as in Fig. 1.

Fig. 3. Antagonistic effects of histamine and DPH on lipid synthesis in chick aortic cells. Primary aortic cells were incubated with the media containing labelled acetate (0.44  $\mu\text{C}/\text{ml}$ .) for 6 h. The black and hatched columns indicate synthesized total lipids and free sterol respectively. Statistical comparisons were made between the group treated with histamine only and the groups treated with both histamine and DPH. \*  $P < 0.05$ . \*\*\*  $P < 0.001$ .

interfered with the histamine suppressing effect. Pre-treatment of cells with histamine for 2 days followed by another 2 day interval of only fresh MEM or DPH in MEM were compared with the d.p.m./μg of total lipids of controls. The results showed, after the 4 day treatment schedules: histamine 64 per cent of control value; DPH plus histamine approximately 100 per cent.

Although these data show an effect of histamine on lipid synthesis it must be emphasized that only cells from chick aortas have been observed. The effect of histamine on cells from other organs and other species must also be investigated.

The demonstration of interference of histamine effect by DPH could be valuable in elucidating the mechanism of action of histamine in intercellular lipid synthesis. Furthermore, these data represent a simple rapid method for surveying compounds that have antihistamine potentials. The question of how these data may be related to the total organism and the development of hypersensitivity and possibly atherogenesis needs considerable attention.

### Optical Rotatory Dispersion of Complexes of Native DNA and Helical Poly- $\alpha$ -L-glutamic Acid with Proflavine

RECENTLY, Blake and Peacocke<sup>1</sup> reported the appearance of an induced Cotton effect in the complex of deoxyribonucleic acid (DNA) with proflavine. The magnitude of the trough at 452  $m\mu$  was almost twice as large as that of the peak at 480  $m\mu$ . They considered the absorption band of the complex to be associated with a single electronic transition and made it appear that the anomalous optical rotatory dispersion (ORD) induced by the bound dye was a single rather than a multiple Cotton effect. Their interpretation of the observed Cotton effect challenges theories of optical activity which predict a single Cotton effect associated with a single circular dichroic (CD) band nearly symmetric with respect to either the centre of the CD band or the inflexion point of the ORD (refs. 2–4). We propose an alternative interpretation, which is in harmony with existing theories, of the ORD results of Blake and Peacocke.

In Fig. 1 an ORD curve of a solution of DNA plus proflavine is shown together with the absorption spectra. The experimental conditions are essentially those of Blake and Peacocke. The observed rotation is expressed in terms of the molar rotation. The general shape of the ORD resembles that of Blake and Peacocke but there are several discrepancies between the two curves with regard to the positions of the peaks and trough as indicated in Table 1a. The most important difference is found in the wavelength region below that of the trough. Going towards shorter wavelengths, the ORD curve approaches zero rotation between 420–400  $m\mu$  and then becomes increasingly negative below 400  $m\mu$ ; this detail is missing in the curve given by Blake and Peacocke.

The presence of two peaks and a trough in the region of anomalous dispersion certainly rules out, according to existing theories, the probability of there being but a single Cotton effect. The complexity of the experimental curve indicates a degree of multiplicity. In addition, the absorption spectrum of the complex shows a shoulder at 425–435 m $\mu$ .

A mixture of sodium poly- $\alpha$ ,L-glutamate (NaPLG) in a helical conformation and proflavine also exhibits extrinsic optical activity throughout the absorption band of the dye (Fig. 1). In contrast to the overt changes noted with DNA, the absorption spectrum of this NaPLG-dye complex shows no new peak or shoulder; nevertheless, the induced Cotton effect is a typical double one with opposite signs. The magnitude of the trough is more than three times that of either of the peaks.

To demonstrate the fact that the induced Cotton effects as observed are not single but multiple, the ORD curves were resolved into their components with the aid of the Kronig-Kramers transform<sup>4</sup> (Figs. 2 and 3, Table 1b).

Fig. 1. Absorption spectra and ORD curves: —, DNA-proflavine, DNA phosphate  $1 \times 10^{-4}$  molar, proflavine  $2.07 \times 10^{-5}$  molar, NaCl  $1 \times 10^{-3}$  molar, pH 6.5; ---, NaPLG-proflavine, NaPLG 3.26 mg/c.c., proflavine  $2.07 \times 10^{-5}$  molar, no salt added, pH 4.5, dye/polymer  $\sim 1$ ; ····, proflavine, no salt added, pH 6.5. A 'Cary Model 60' spectropolarimeter and a 'Cary Model 14' spectrophotometer were used. Due precautions were taken to avoid complications that might arise from instrumental artefacts<sup>5</sup>. The molar rotation of the complex solution in terms of the total dye concentration,  $[R]_C^D$ , is defined as

$$[R]_C^D = \frac{10}{M_D} (\theta_C^P/l_C - \theta_P^P/l_P)$$

where  $M_D$  is the molarity of dye,  $\theta_C^P$  and  $\theta_P^P$  are net rotations in degrees and  $l_C$  and  $l_P$  is the path length in decimetres for complex and polymer solutions. The polymer concentration in both solutions is maintained at the same level.

$$[R] = \sum_k [R]_k = \frac{96N}{hc} \cdot \sum_k \frac{(R_k \lambda_k)}{\Delta_k} \left[ e^{-(\lambda - \lambda_k)^2 / \Delta_k} \cdot \int_0^{\lambda - \lambda_k / \Delta_k} e^{-x^2} dx - \frac{\Delta_k}{2(\lambda + \lambda_k)} \right] + \frac{m}{\lambda^2} \quad (1)$$

where  $[R]$  is the total molar rotation,  $N$  Avogadro's number,  $h$  Planck's constant,  $c$  the velocity of light,  $\lambda_k$  transition wavelength,  $R_k$  rotational strength,  $\Delta_k$  half-intensity band width, and  $m$  a constant. To facilitate calculation, the following assumptions were made. (a) Two partial rotations are necessary to describe fully the observed Cotton effect in the visible absorption band of the bound proflavine; and (b) the CD bands are represented by Gaussian distributions on the wavelength scale, that is,

$$\epsilon_l - \epsilon_r = (\epsilon_l - \epsilon_r)_{\max} \cdot e^{-(\lambda - \lambda_k)^2 / \Delta_k} \quad (2)$$

For the DNA-proflavine system the first component Cotton effect, with an inflexion point at 468 m $\mu$ , has a positive rotational strength. The second one centred at 442 m $\mu$  is of opposite sign and more damped than the first, as the half-intensity band widths indicate. For the NaPLG-proflavine system, the parameters of the positive component Cotton effect at 466 m $\mu$  are similar to those

Fig. 2

Fig. 3

Figs. 2 and 3. Resultant and component curves of ORD and CD for DNA- and NaPLG-proflavine. Filled circles are experimental points. The same symbols are used for the respective ORD and CD curves. Curves 1 and 2 are the component Cotton effects, while curve 3 is the background rotation.  $\Sigma$  is the sum of curves 1, 2 and 3.

\* Deg. cm<sup>2</sup>/molarity dm.

of the negative one at 438 m $\mu$ . It is worth noting that two very diverse helical macromolecules give rise to component Cotton effects the location and rotational strength of which with regard to both sign and magnitude are closely related. Furthermore, the rotational strengths in the two systems studied are quite comparable with those obtained for helical polypeptides<sup>6</sup>. A weak background rotation expressed by the last term in equation (1) was added in each case, because a slight alteration in the conformation of the polymer may result when dye is bound; and the influence of a strong absorption band of the bound proflavine around 257 m $\mu$  should be taken into consideration. The resultant CD curves computed from the component Cotton effects are given at the bottom of Figs. 2 and 3.

The resultant Cotton effect, calculated from components, agrees surprisingly well with those measured for the two systems. The possibility exists that the second Cotton effect of DNA-proflavine may not be single, but a composite of two closely overlapping effects of like sign. This does not in any way detract from our present proposition, because it is now evident that the observed extrinsic Cotton effect consists of at least two components of opposite signs. This is the case in spite of the fact that the observed absorption spectra do not clearly indicate the electronic transitions involved.

Peacocke and Skerrett<sup>8</sup> found that values of  $r$ , the number of proflavine molecules bound per phosphate residue of DNA, determined by equilibrium dialysis, agreed with those calculated from optical density measurements in the range 430-440 m $\mu$ , but not with those based on data at 460 m $\mu$ . They concluded that the optical density at 460 m $\mu$  for DNA-proflavine must vary with values of  $r$ . This observation suggests that the absorption band of the dye in the complex is heterogeneous and that at least two optical transitions are involved. This is consistent with our results. It seems likely that a positive Cotton effect at 468 m $\mu$  may be associated with an electronic transition around 460 m $\mu$  and that a negative Cotton effect at 442 m $\mu$  may correspond to the transition between 420 and 440 m $\mu$ . The origin of these suggested optical transitions for both DNA- and NaPLG-proflavine complexes must await further studies. Detailed work on the absorption spectra of proflavine itself should precede the final assignment<sup>7</sup>.

We thank Dr. E. Charney of this laboratory for his helpful discussion.

## New Leuco-anthocyanins in Grasses

EXAMINATION of the leaves of a series of grasses in the usual way<sup>1</sup>, which involves hydrolysing the leaves in 2 normal hydrochloric acid and extracting the hydrolysate with isoamyl alcohol, showed in four of them the presence of a component giving rise to a scarlet-coloured anthocyanidin having an  $R_f$  of 0.62 in Forestal solvent (acetic acid : concentrated hydrochloric acid : water, 30 : 3 : 10 by volume). The extract, diluted with methanol, had  $\lambda_{\max}$  between 496 and 502 nm, indicating its probable identity with luteolinidin ( $R_f$  0.62 in Forestal,  $\lambda_{\max}$  in methanol 496 nm (ref. 2)). It thus seems that the four grasses contain a leucoluteolinidin. It is unlikely that such a compound could have a flavan-3,4-diol structure, but the flavan-4-ol (4,5,7,3',4'-pentahydroxyflavan) produced by reduction of eriodictyol with sodium borohydride (unpublished results of T. Swain) and a methanolic extract of the grasses behaved identically both when boiled with 2 normal hydrochloric acid (yielding luteolinidin) and when treated with cold concentrated hydrochloric acid. In the latter case a blue colour was produced with  $\lambda_{\max}$  550 nm, the product responsible being, perhaps, the carbonium ion of the ring-opened form of the flavan<sup>3</sup>. On standing, or after dilution and heating, this was partially converted into luteolinidin. It should be noted that other flavan-4-ols show similar behaviour<sup>3</sup>, but flavan-3,4-diols (for example, leucocyanidin), although giving an intermediate blue-purple component when heated in 2 normal hydrochloric acid, do not give such a colour with cold concentrated acid.

The progenitor of luteolinidin in the grasses is not, however, a simple flavan-4-ol, because when methanolic extracts are chromatographed in either aqueous or alcoholic solvents, and chromatograms are sprayed with concentrated mineral acid (or with vanillin-sulphuric acid), the blue (or purple) coloration which develops is confined to the start-line. It seems probable that the precursor is a polymer of similar constitution to that recently proposed for the flavan-3,4-diol polymers<sup>4,5</sup>, and could, like these, have the properties of a condensed tannin.

In addition to the above compound, the hydrolysed extracts of two of the grasses had a second, fainter, reddish spot with  $R_f$  0.80 in Forestal, very near to that, 0.78, of apigeninidin and tricinidin<sup>2</sup>. That it is not the former is indicated by its reddish colour (apigeninidin being yellow) and the absence of an absorption peak lower than 496 nm (apigeninidin  $\lambda_{\max}$  476 nm). The possibility remains open, therefore, that the anthocyanidin is tricinidin.

Most of the above observations refer to *Hyparrhenia filipendula* (Hochst.) Stapf. The other species containing leucoluteolinidin were *Imperata cylindrica* (Linn.) Beauv. var. *africana* (Anderss.) Hubbard, *Themeda triandra* Forsk., and a *Bothriochloa* species, probably *B. insculpta* (Hochst. ex. A. Rich.) A. Camus, the first of these also containing the tricinidin precursor. All these genera are placed in the tribe Andropogoneae. Two other members of this tribe, *Andropogon gerardii* With. and

*Hyparrhenia hirta* Stapf, had been observed to yield anthocyanidins with  $R_f$  0.62 and 0.66, respectively, in Forestal solvent<sup>4</sup>, the only species out of more than sixty of the Gramineae examined to have such constituents. It is interesting to note that Stafford<sup>7</sup> has recently reported the occurrence of luteolinidin itself in seedlings of *Sorghum vulgare* Pers., a member of the same tribe. Blessin *et al.*<sup>8</sup> earlier showed leuco-anthocyanins to be present in the pericarp of certain varieties of sorghum; the  $R_f$  values of one of the anthocyanidins produced, tentatively identified as fisetinidin, are consistent with its being luteolinidin. Yasumatsu *et al.*<sup>9</sup>, on the other hand, reported the presence of a leuco-anthocyanin yielding pelargonidin from the seed coat of a commercial sample of sorghum (variety unspecified).

We are indebted to Dr. J. B. Harborne for gifts of luteolinidin and tricinin.

### Potassiumless Death of *Saccharomyces cerevisiae* Cells treated with *N*-Succinyl Perimycin and the Reversal of Fungicidal Action of the Antibiotic by Potassium Ions

*N*-SUCCINYL PERIMYCIN<sup>1</sup> is a synthetic derivative of heptaene macrolide antifungal antibiotic<sup>2</sup>. The advantage of this substance is that, unlike the original polyenes, it forms readily water soluble salts, for example, the sodium salt, which retain much of the activity of perimycin itself<sup>1,3</sup>. The critical site of action of polyenes in general is the cell membrane and the lethal effect of these substances is a result of an impairment of the membrane's function<sup>4-12</sup>.

The sensitive organisms have a rather high polyene binding capacity because of the presence of a specific binding site in the membrane which is supposed to be a membrane lipid, presumably a membrane sterol<sup>9,13-15</sup>. The reorientation of the membrane lipid layer by the bound polyene<sup>14</sup> brings about the change of permeability properties. The impairment of the osmotic barrier and transport systems decreases the ability of the membrane to take up and retain a number of critical metabolites, which in consequence leads to the death of the cell.

The degree to which the membrane can be damaged depends on the structure of a given polyene, as well as on its concentration. The whole spectrum of permeability changes has been observed with various polyenes used in various concentrations. The higher the molecular weight of a polyene and the lower its concentration the more permeability changes are restricted to

fewer metabolites of decreasing molecular weight, including inorganic ions, of which the most important is the potassium ion<sup>4,6</sup>. Nevertheless, none of these antibiotics induced an effect restricted to a specific metabolite, which could be reversed and the fungicidal action annulled by the addition of this metabolite to the medium. Inhibition caused by polyenes has so far been reversed for some enzyme systems only, on the addition of metabolites which leak from the cells treated with polyene, but reversal of the fungicidal action of the antibiotic has not been achieved. Thus, for example, the addition of potassium salts to the medium caused the resumption of glycolytic activity which was inhibited by polyenes the action of which was proved to be more specific<sup>10,11,16</sup>. Less specific polyenes required the addition of potassium and a number of glycolytic cofactors for the restoration of the anaerobic breakdown of glucose<sup>4</sup>.

We have shown that the impairment of membrane permeability properties by *N*-succinyl perimycin is the most specific of all polyenes<sup>17</sup>. Conditions were found in which the damage of the osmotic barrier with respect to potassium ions was the only demonstrable effect of the antibiotic. No permeability changes were observed with respect to organic metabolites.

The specific escape of potassium from cells treated with *N*-succinyl perimycin in potassium deficient medium causes, first, inhibition of metabolic activity of potassium dependent systems. Other metabolic reactions which are not potassium dependent or which are dependent to a lesser extent are not inhibited.

The suppression of activity of potassium dependent systems, while other reactions are not inhibited, probably induces a metabolic disequilibrium, which is the proposed explanation for the subsequent death of the cells. This phenomenon has been named by us "potassiumless death". The presence of the substrate in the medium significantly enhances potassiumless death caused by the more strongly unbalanced metabolic activity of the cells. Potassiumless death is also enhanced by sodium ions, as a result of the facilitated removal of potassium from cells which results from potassium-sodium exchange.

The high specificity of action of *N*-succinyl perimycin permitted restoration of the activity of potassium dependent systems by the addition to the medium of potassium salts in concentration approximately equal to that found in cells plasma.

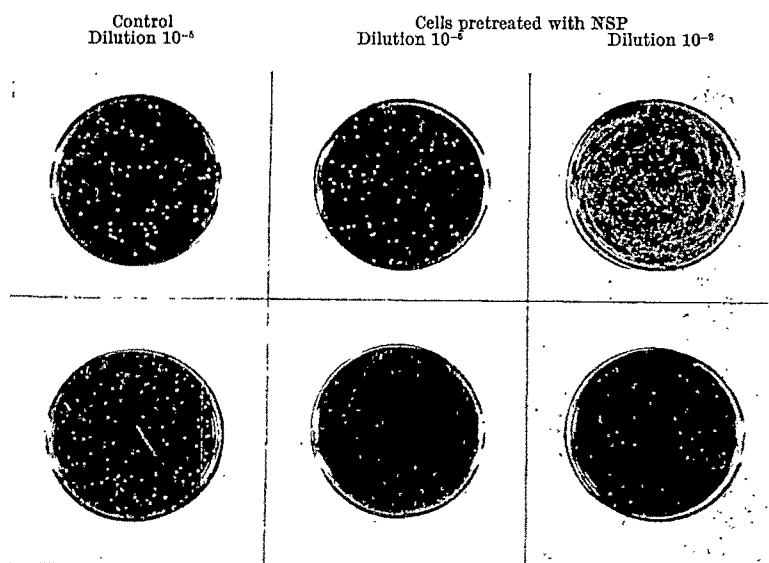

Fig. 1. Potassiumless death of *Saccharomyces cerevisiae* cells damaged by *N*-succinyl perimycin (NSP) and the regeneration of damage and restoration of viability in the presence of potassium ions. Top row, agar with 0.1 molar potassium ion. Bottom row, agar without potassium ion.

Evidence will be given for the annulment of fungicidal action of *N*-succinyl perimycin by potassium ions. *Saccharomyces cerevisiae* strain ATCC 9763 was used as the model organism. *N*-succinyl perimycin was applied in the form of water soluble sodium salt. Logarithmic cells were prepared by culturing *Saccharomyces cerevisiae* for 16 h at 30° C in a medium of the following composition: 0.3 per cent 'Bacto'-yeast extract, 0.5 per cent 'Bacto'-peptone 'Difco', 1 per cent glucose. The medium was inoculated with an agar slant culture grown on a medium of the same composition. After 16 h of incubation the culture was diluted five-fold with fresh medium and reincubated for a further 4 h. Cells were collected by centrifugation and washed three times with distilled water. A cell suspension (4 mg/ml, dry weight) was prepared in *tris*-hydrochloric acid buffer, pH 7.2, containing 0.1 molar potassium chloride, and incubated without (control) and with 10 µg/ml. sodium salt of *N*-succinyl perimycin for 2 h at 30° C with shaking. Each suspension was then divided in two parts and processed separately. One part was centrifuged, washed once with 0.1 molar potassium chloride and after making serial dilutions 0.1 ml. aliquots were plated on agar medium (1 per cent 'Bacto'-peptone, 2 per cent glucose, 0.1 molar potassium chloride). The second part was processed similarly, except that it was washed with distilled water instead of 0.1 molar potassium chloride and cells were plated on agar without added potassium salt (medium contained trace quantities of potassium ion from reagents of concentration approximately 0.0005 molar). All plates were incubated for 36 h at 30° C and colonies were counted. The results are shown in Fig. 1 and Table 1.

Table 1. REVERSAL OF FUNGICIDAL ACTION ON *N*-SUCCINYL PERIMYCIN BY POTASSIUM IONS

Medium for viable cell count	Viable cells/ml. 10 µg of sodium salt of <i>N</i> -succinyl perimycin/ml.	
	Control	
Agar with 0.1 molar potassium ion	1 × 10 <sup>8</sup>	8 × 10 <sup>7</sup>
Agar without potassium ion	1 × 10 <sup>8</sup>	2.5 × 10 <sup>4</sup>

The count of cells not treated with *N*-succinyl perimycin is identical on both agar media. Cells treated with the antibiotic did not give at dilution 10<sup>-5</sup> any colonies on agar without potassium, but about 80 per cent colonies, as compared with the control, on agar containing 0.1 molar potassium chloride. A small percentage of cells was unaffected by the antibiotic, which can be seen after plating more concentrated cell suspension on agar without potassium salt. The figures in Table 1 show that only 0.025 per cent of cells were unaffected by *N*-succinyl perimycin. This percentage could be reduced to zero after longer treatment with the antibiotic.

The cells treated with *N*-succinyl perimycin and grown on the agar with potassium salt are identical with the original strain. They grow well when transferred to agar without potassium, which proves that they are fully regenerated. No difference in sensitivity to *N*-succinyl perimycin has been observed. Inhibitory concentration of the antibiotic in streak dilution agar plates method (medium: 1 per cent 'Bacto'-peptone; 2 per cent glucose, 2 per cent agar) was identical for both strains and equal to 0.5 mcg/ml. This proves that the treated cells did not acquire the resistance.

The cells treated with *N*-succinyl perimycin and plated on agar with potassium chloride grow slowly at first in comparison with the untreated ones. This delay is probably a result of the time required for the regeneration of damage caused by the antibiotic.

Further investigations aimed at a more detailed explanation of the phenomenon of potassiumless death are in progress. The biological properties of *N*-succinyl perimycin encourages us to consider this antibiotic as a tool for investigations of the mechanism of potassium transport systems.

This communication was presented at the third meeting of Federation of European Biochemical Societies, Warsaw,

1966, under the title of "Studies on the Mode of Action of *N*-succinyl Perimycin".

## PATHOLOGY

### Circulating Cell as a Source of Myoblasts in Regenerating Injured Mammalian Skeletal Muscle

THE theory that injured skeletal muscle can regenerate by the formation of new cells although still disputed<sup>1</sup> has strong support<sup>2-4</sup>. New muscle fibres are held to develop from multinucleate "myotubes" which are formed either by the budding of damaged muscle fibres or more probably by the fusion of mononuclear cells which have been termed "myoblasts"<sup>5-8</sup>. Walker insists that myoblasts multiply solely by mitotic division and derives them from injured adult muscle cells by dedifferentiation. Later cytoplasmic differentiation occurs mainly in myotubes and in these nuclear division is no longer seen. Others have claimed that myoblasts originate in connective tissue cells in or near the site of injury. It occurred to us, however, that like leucocytes and phagocytic histiocytes<sup>9</sup> these muscle precursors could be carried in the circulation to injured areas from a central source, for example, the lymphoid tissues or bone marrow.

To test this hypothesis we injected 50 µc. of tritiated thymidine (6-T(n), specific activity 5.0 c./mmole) intraperitoneally four times successively at 6 h intervals into female adult mice. In one pair, crush lesions<sup>10</sup> were made in the right gastrocnemius 48 h after the fourth injection of radioisotope, that is, at a time when there should be, in the blood stream, no tritiated thymidine, because this material is taken up by cells preparing for mitosis and almost entirely disappears from the circulation within an hour of injection<sup>11</sup>. In six further animals, the right gastrocnemius was crushed at varying periods after the left, because it seemed possible that the regeneration process in one leg could be modified by a preceding muscle injury in the other (see Table 1). The first injection of tritiated thymidine was given to these animals 6 h after the left gastrocnemius was crushed. Intervals of 12, 24 and 48 h elapsed between the fourth injection and the crushing of the right gastrocnemius. All mice were killed 8 days after injury to the right gastrocnemius.

Table 1. TRITIATED THYMIDINE UPTAKE BY NUCLEI OF MYOTUBES IN REGENERATING MUSCLE  
Grain counts/myotube nucleus in left leg

Time between fourth injection of tritiated thymidine and injury to right leg	Median	Range	Proportion of nuclei with one grain or more (per cent)	Median	Range	Proportion of nuclei with one grain or more (per cent)
48 h*	0	0-3	11	6	0-31	86
	0	0-1	1	8	0-30	85
12 h†	5	0-21	82	6	0-22	87
24 h†	6	0-19	91	8	0-24	93
	8	0-34	87	6	0-24	93
48 h†	6	0-20	83	4	0-21	73
	8	0-31	93	7	0-31	93
	12	0-34	84	5	0-24	79

\* Left leg uninjured.

† Left leg injured 6 h before first injection of tritiated thymidine.

Note that the pattern of nuclear labelling differs little in the successively injured left and right legs of individual mice.

In autoradiographs from sections of both gastrocnemii embedded in paraffin, grain counts were made over 150 nuclei belonging either to myotubes at injury sites, or, in the first pair of mice, to normal muscle fibres. Over occasional nuclei in uninjured muscle fibres there was one grain, and over three nuclei there were two or three grains. Conversely, in injured muscle a wide variety of cells was heavily labelled. Grain counts (see Table 1) over the myotube nuclei ranged between none and thirty-four except for two nuclei where forty-two and fifty grains were seen. Medians varied between four and twelve, the percentage of nuclei with one or more granules between seventy-three and ninety-three. Myotube nuclei were thus intensely labelled while the nuclei of cells in uninjured muscle were in effect unlabelled. Grain counts made over connective tissue cells between normal muscle fibres similarly indicated that these were, with rare exceptions, unlabelled. These exceptions had five, eleven, and twenty-six grains respectively and were included in an analysis of 300 cells.

The most striking finding in the first pair of mice was the presence of intensely labelled nuclei in myotubes of the right leg. This was unexpected, for Bintliff and Walker<sup>9</sup> had maintained that tritiated thymidine, injected before injury, labelled inflammatory cells but not the precursors of regenerating muscle fibres. These workers, however, gave the thymidine three times in 12 h, whereas our injections were made four times in 24 h, a procedure which was more likely to allow for diurnal variations in mitotic activity. Because uninjured muscle was not labelled, the labelling of myotubes so long after tritiated thymidine injection strongly suggested the immigration into the lesion of an already labelled precursor.

A similar immigration of labelled cells probably accounted for the intense labelling of myotubes in the right or second injured leg. If these cells had migrated from the left or first injured leg, one would anticipate a dilution of their labelling after each subsequent cell division. This was not observed because the intensity of labelling in the right and left legs differed little, even when 12 or 24 h separated the last injection of tritiated thymidine from the time when the second leg was injured.

One possible explanation for our findings is to suppose that dividing myoblasts can reutilize labelled nucleoprotein derived, for example, from dead neutrophil leucocytes<sup>7</sup>. This concept of reutilization is difficult to reconcile with the similarity in pattern and intensity of myotube labelling in successively injured legs in our experiments, because myoblasts in the second injured leg would tend, if labelled by reutilization of thymidine, to be far less heavily labelled than those myoblasts in the first injured leg which were directly labelled by circulating recently injected thymidine.

Another explanation is that thymidine persists in tissue in a soluble form, demonstrable in frozen sections<sup>12</sup>, but largely lost from sections of tissue embedded in paraffin. This is possible, but would scarcely explain the intensity of labelling we observed in second injured legs in our experiments.

It is concluded, therefore, that many myoblasts or their precursors probably migrate into muscle lesions from the blood stream. This concept is at variance with current views on muscle regeneration. It follows that in those muscle diseases in which a disorder of regeneration has been postulated, therapy may have to be directed not so much to the affected muscles as to the body as a whole, that is, to the source of muscle cell precursors.

We thank the Muscular Dystrophy Trust of Great Britain, supported by the Sembal Trust, and the Clinical Research Sub-Committee of Charing Cross Hospital for supporting this work.

### Effects of Corticoid Injection and of Adrenalectomy on *in vitro* Amino-acid Incorporation into Microsomes of P1798 Lymphosarcoma

THE involution of lymphoid tissue which follows administration of corticoids to animals could be a result of more rapid cell destruction or inhibition of an anabolic process. An increase in ribonuclease after injection of corticoid has been shown in corticoid-sensitive P1798 lymphosarcoma<sup>1</sup>, and in rat thymus<sup>2</sup>. This change is measurable 6 h or more after administration of cortisol. Enhanced ribonuclease activity could result in diminished protein synthesis.

Decreased incorporation of amino-acids into microsomes of rat thymus and mouse lymphoma ML388 3 and 12 h after treatment with cortisol has been demonstrated<sup>3,4</sup>. This inhibition could cause the involution of lymphoid tissue which follows administration of cortisol to animals. To test this possibility preliminary observations were made of the inhibition of amino-acid incorporation into microsomes of lymphosarcoma P1798. This tumour has a more uniform cell population than thymus and is available in corticoid sensitive and resistant strains<sup>5</sup>, so that the inhibition could be correlated with *in vivo* sensitivity. Steroid treatment of mice

bearing corticoid sensitive tumour gave microsomes with a marked deficit for incorporation of phenylalanine which was not relieved by the addition of polyuridylic acid (poly-U) to the incubation mixture. There was no such inhibition after treatment of mice bearing the corticoid resistant strain tumour. When glucocorticoid was administered to adrenalectomized mice bearing steroid sensitive tumour, no inhibition of incorporation into microsomes was observed.

Corticosteroid sensitive and resistant lymphosarcoma P1798 was transplanted into BALB/c mice as previously described<sup>1</sup>. 9- $\alpha$ -fluoro-prednisolone (9FP) and steroid suspending vehicles were supplied by the Cancer Chemotherapy National Service Center. Uniformly labelled phenylalanine-<sup>14</sup>C was used.

The preparation of tumour microsomes and the measurement of incorporation were adapted from the methods of Ochoa and Weinstein<sup>2</sup>. To restrict the observed hormonal effects to the microsomes and to avoid introduction of ribonuclease known to be present in the tumour supernatants, supernatant fraction from normal mouse liver was used in the incubation mixture. Microsomes were incubated for 15 min at 37° C in 0.01 molar *tris*, pH 7.4, 0.05 molar magnesium acetate, 0.06 molar potassium chloride, 0.025 mmolar GTP, 0.625 mmolar ATP, 3.12 mmolar PEP, 12  $\mu$ g of pyruvate kinase, 0.01 ml. of a mixture of twenty amino-acids excluding phenylalanine, each 0.0125 mmolar, 0.1  $\mu$ c. of phenylalanine-<sup>14</sup>C (specific activity > 300 mc./mmoles), 0.006 molar mercaptoethanol, and 0.4–0.5 mg of protein of supernatant fraction from normal mouse liver in a total volume of 0.4 ml. In these circumstances, incorporation was proportional to the amount of microsomal protein present and 0.3–0.4 mg was used in these experiments. Protein was determined by the method of Lowry *et al.*<sup>3</sup>. The concentration of magnesium ions used was optimal for both treated and untreated fractions. Poly-U, when present, was added to a final concentration of 250  $\mu$ g/ml. which was found to give maximal stimulation. Incorporation of phenylalanine was decreased 18 h after the administration of 9FP to mice bearing sensitive tumours. No such decrease was observed when resistant tumours were investigated. Table 1 also shows that the incorporation is similar in the controls from the two strains and is increased by the addition of poly-U which, however, did not prevent the inhibition after treatment.

Table 1. INCORPORATION OF PHENYLALANINE INTO TUMOUR MICROSOMES ( $\mu$ moles/mg of microsomal protein  $\pm$  S.E.M.)

Tumour	Without poly-U	With poly-U
Sensitive control	0.81 $\pm$ 0.09	5.6 $\pm$ 0.4
Sensitive treated	0.34 $\pm$ 0.08 ( $P < 0.01$ )	2.6 $\pm$ 0.2 ( $P < 0.01$ )
Resistant control	0.74 $\pm$ 0.09	5.7 $\pm$ 0.6
Resistant treated	0.89 $\pm$ 0.11 ( $P < 0.3$ )	5.1 $\pm$ 0.8 ( $P < 0.04$ )

Six separate microsomal preparations were made for each of the four tumour groups. Treatment consisted of subcutaneous injection of 0.2 ml. of suspending medium alone or containing 25 mg/kg of 9FP, 18 h before killing.

Repetition of this experiment 2, 4, 6 and 12 h after administration of corticoid failed to demonstrate inhibition, although inhibition 18 h after treatment could be demonstrated consistently.

The effect of administration of 9FP on phenylalanine incorporation into tumour microsomes was also evaluated in mice after adrenalectomy. Table 2 shows that the inhibition after corticoid administration was not found in adrenalectomized mice.

Six separate microsomal preparations were made in each group. Adrenalectomy was performed 8 days before.

Table 2. INCORPORATION OF PHENYLALANINE INTO TUMOUR MICROSOMES FROM ADRENALECTOMIZED MICE ( $\mu$ moles/mg of microsomal protein  $\pm$  S.E.M.)

Tumour	Without poly-U	With poly-U
Sensitive control	0.58 $\pm$ 0.03	4.82 $\pm$ 0.6
Sensitive treated	0.94 $\pm$ 0.09 ( $P < 0.01$ )	5.0 $\pm$ 0.2 (N.S.)
Resistant control	1.05 $\pm$ 0.07	4.4 $\pm$ 0.5
Resistant treated	1.50 $\pm$ 0.05 ( $P < 0.01$ )	6.9 $\pm$ 0.2 ( $P < 0.01$ )

Treatment and incubation conditions were identical with those in Table 1. The increased incorporation after treatment with corticoid in this experiment was not found consistently.

Lymphosarcoma P1798 is useful in investigations of the mechanism of steroid-mediated lymphocytolysis. It has far fewer non-lymphoid elements than thymus and is available in glucocorticoid sensitive and resistant strains. This latter property is a great advantage for delineation of biochemical effects relevant to breakdown mediated by steroid. The inhibition of incorporation of phenylalanine into microsomes of corticoid sensitive tumour was not observed before 18 h. This is later than the inhibition observed previously<sup>4</sup> for thymus 3 h after cortisol treatment. It is not known, however, whether lymphoid or thymic epithelial elements were involved in the inhibition. Involution of P1798 sensitive to steroid becomes just apparent about 18 h after treatment. Failure of the steroid resistant strain to demonstrate inhibition of phenylalanine incorporation following steroid treatment suggests that the decreased incorporation in the sensitive strain is either relevant to the mechanism of lymphocytolysis or secondary to that process. Even within the microsomal particle, presumably increased pools of amino-acid secondary to glucocorticoid mediated lymphoid catabolism could account for decreased incorporation. Failure of glucocorticoid treatment to result in decreased incorporation in adrenalectomized animals is not explained by our current data. Adrenalectomized animals show impressive involution of steroid sensitive tumour after glucocorticoid treatment and this suggests that inhibition of incorporation of amino-acid is not a necessary feature of glucocorticoid mediated lymphocytolysis.

## Biochemical and Histochemical Observations on Aminopeptidase Activity in Early Wound Healing

LACK of investigations into the earliest phase of healing has supported the prevalent view that an inert lag period occurs up to the third or fifth day after wounding. Histochemically, however, the activity of several hydrolytic, transferring and oxidative enzymes has been demonstrated to increase during the very first post-operative hours<sup>1–3</sup>. An increase in aminopeptidase activity is histochemically demonstrable 2 h after the injury<sup>4</sup>. We have also investigated this enzyme biochemically during the earliest phase of wound healing.

We made an experimental biochemical investigation on rats, excising square, 1 cm<sup>2</sup> skin wounds in a shaved dorsal area. The wounds were neither sutured nor dressed. Four groups of animals were killed 0.5, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 16, 20, 24, 32 and 48 h after wounding, and a flap of skin containing the wound was removed. The tissue surrounding a wound excised 15 min before the death of each rat served as a control for the animal. The skin flaps were frozen fresh with solid carbon dioxide. One hundred sections, 16 $\mu$  in thickness, were cut in a cryostat

at  $-20^{\circ}\text{C}$  from each edge of the quadrangular wounds. The 400 sections per one wound were ground in 3 ml. of 0.01 molar *tris* hydrochloric acid buffer (pH 7.15) at  $4^{\circ}\text{C}$  with an 'Ultra-Turrax' homogenizer for 5 sec, and the mixture was then centrifuged at 23,500g for 10 min. The supernatant was assayed for aminopeptidase activity by a colorimetric method<sup>4</sup>. For comparison, some cryostat sections were used for the histochemical<sup>5</sup> demonstration of the enzyme.

During the two first post-operative hours aminopeptidase activity decreased biochemically (Fig. 1). Thereafter, a gradual increase in activity was observed. This intensification was sharpest from 2 to 7 h after the injury. Also histochemically, an increase in aminopeptidase activity could be demonstrated 2 h after the operation, gradually increasing thereafter (Fig. 2). In the immediate vicinity of the wound edge, a central zone, 200 to 500  $\mu$  in depth, showed decreasing enzyme activity. Surrounding this, a 100 to 300  $\mu$  deep peripheral wound zone exhibited a progressive increase in aminopeptidase activity after 2 h.

The initial decrease in enzyme activity could be caused by a traumatic inhibitory effect on the enzyme or on its synthesis. The cells in the superficial (central) wound zone, being too severely damaged, are not able to show any increased enzyme activity later on<sup>2,3</sup>. On the other hand,

the trauma affecting the connective tissue cells in the peripheral wound zone seems to serve as a stimulus, activating defence forces after a short mobilization time. Thus, the initial increase in enzyme activity in this zone probably represents an adaptive defence mechanism by the local cells as a response to injury<sup>3</sup>. Active leucocytes invade the peripheral zone after 8–16 h<sup>6</sup>. The initial increase in aminopeptidase activity might be connected with the peptides that are shown by Menkin<sup>7</sup> to give rise to local hyperaemia, increase in capillary permeability, and migration of leucocytes.

This investigation was supported by a research grant from the Sigrid Jusélius Foundation.

### Influence of Pineal Body on Melanoma of Hamsters

JORDAN<sup>1,2</sup> described the presence of melanic granules in pineal gland of sheep and del Rio-Hortega<sup>3-5</sup> found pigment granules in the pinealocytes of human pineal as well as in other mammals. Santamarina and Meyer Arndt<sup>6</sup> have more recently shown that the pigment in bovine pineal was true melanin. Ultra-violet spectral curves of bovine pineal melanin showed the same characteristics as those obtained from tyrosine melanin<sup>7,8</sup>. Pineal melanin differs slightly, however, from the melanin obtained from the choroid of the ox eye. Administration of pineal extract to tadpoles<sup>9,10</sup>, to toads<sup>10</sup> and to fishes<sup>11</sup> produces alteration in pigmentation. Thus it is possible that pineal body not only contains melanic pigment but is also capable of inducing some form of change in pigmentation. The hamster pineal body contains pigment granules in abundance (Fig. 1). On the basis of the investigations by Santamarina and Meyer Arndt, these can be assumed to be melanic granules. No data are available at present for the effects of pineal ablation or administration of pineal extract on pigmentation of hamsters. Isolated observations in other species have suggested a possible association between pineal body and pigmentation, however, and therefore a study was undertaken to observe the effect of pineal ablation on the growth and spread of a highly pigmented and spontaneously occurring neoplasm in hamsters.

Syrian hamsters of both sexes weighing between 80 and 110 g were used. Thirty-eight hamsters were pinealec- tomized according to a technique developed in this laboratory<sup>12</sup>. Thirty-six hamsters were subjected to comparative trauma and bleeding but the pineal gland and its stalk were left undamaged and intact. The remaining forty animals were used as controls. All animals were fed standard laboratory diet and water *ad libitum*. Five weeks after either surgical procedure hamsters were considered ready for tumour transplantation.

Melanotic melanoma No. 1 (M. Mel 1—kindly supplied by J. G. Fortner) was chopped into small pieces and 0.4 ml. injected through a large bore needle into the subcutaneous tissue of the dorsum of each of the experimental hamsters. After inoculation, measurements of hamsters' weight, mean tumour diameter and time of appearance of skin ulceration were recorded every 2 days, until the animals

were killed. Hamsters from the first group were killed 14 days after tumour transplantation and subsequent groups 21, 28 and 35 days after the inoculation. All animals were autopsied and the findings are recorded in Table 1. The presence of metastatic deposits were confirmed by histological examination; however, in most cases the metastases could be diagnosed on gross examination alone.

The first part (A) of Table 1 describes the observation at autopsy on the fourteenth day of tumour transplantation. The mean tumour diameter was 1.47 cm in pinealectomized, 0.7 cm in sham-operated and 0.6 cm in the control group. The increase in diameter of the tumours in pinealectomized hamsters as opposed to the other two groups is highly significant ( $P < 0.001$ ). But the difference between control and sham-operated groups was also significant ( $P < 0.02$ ). This is the only set where the tumour diameter difference was significant between control and sham-operated animals. A similar difference was found in the incidence of metastatic deposits in these three groups of animals. This trend of highly significant differences in tumour diameters ( $P \leq 0.001$ ) and incidence of metastases ( $P < 0.005$ ) between the pinealectomized hamsters and the other two groups after 3, 4 and 5 weeks of tumour transplantation is apparent in Table 1.

These results suggest that ablation of the pineal gland alters the course of pigmented melanoma in Syrian hamsters. The effect of pinealectomy on the course of melanoma seems to be more apparent during the earlier part of the growth of this tumour. The validity of these experimental results depends on the accuracy of the measurement of different parameters. All the animals in each group were transplanted and killed at the same time so the question of time interval and appearance of metastases or the size of the primary tumours could be accurately checked. Inclusion of a sham-operated group automatically enabled a further check to be made of the

Table 1. RESULTS OF AUTOPSY AT REGULAR INTERVALS

No. of hamsters in each group	Tumour diameters mean $\pm$ S.E.* (cm)	No. of ulcer- ations of primary tumour	Metastatic pattern†				Axil- lary node
			Lung	Liver	Kid- ney	Spleen	
(A) 14 days after tumour inoculation							
Control (10)	0.59 $\pm$ 0.12	1	1	0	0	0	3
Sham-operated (10)	0.72 $\pm$ 0.95	3	2	0	0	0	3
Pinealectomized (10)	1.47 $\pm$ 0.16	8	7	2	6	2	8
(B) 21 days after tumour inoculation							
Control (10)	1.63 $\pm$ 0.39	3	1	0	0	0	3
Sham-operated (10)	2.03 $\pm$ 0.27	4	1	0	0	0	4
Pinealectomized (12)	3.35 $\pm$ 0.34	11	9	4	7	2	8
(C) 28 days after tumour inoculation							
Control (10)	2.4 $\pm$ 0.27	5	3	0	0	0	5
Sham-operated (10)	2.42 $\pm$ 0.10	7	4	0	1	0	4
Pinealectomized (8)	4.0 $\pm$ 0.34	8	8	3	5	1	7
(D) 35 days after tumour inoculation							
Control (10)	3.5 $\pm$ 0.23	7	6	0	3	0	7
Sham-operated (6)	3.5 $\pm$ 0.82	5	4	0	4	0	6
Pinealectomized (8)	5.3 $\pm$ 0.13	8	8	3	7	2	8

\* Tumour diameter in pinealectomized animals as compared with those which were sham-operated was  $P < 0.001$ . (In group A only the difference in diameter between control and sham-operated animals was significant at the  $P < 0.02$  level. In the remaining groups the difference between control and sham-operated was insignificant, whereas the difference between pinealectomized animals and the sham-operated and control animals was highly significant in each group.)

† The figures shown represent the number of times each viscus has been involved. Comparison of the percentages of metastatic involvement of any sites in pinealectomized hamsters in each group was highly significant (for example, in lung  $P < 0.005$  (14 days), 21 days and 28 days, respectively).

effect of pinealectomy in these experiments. The interval of 5 weeks between any surgical trauma and tumour inoculation obviates the possible effect of trauma. The significant difference in the size of the tumours observed in group A between control and sham-operated animals remains to be explained.

The pinealectomized animals weighed more than the other two groups of hamsters at the time of killing. This could either result from pinealectomy *per se* or the increased mass of the tumour or both. From these experiments no statement can be made.

Fig. 1. Longitudinal section of a hamster pineal gland. A nucleus of a pinealocyte (P. Nu) is present at the bottom left-hand side. Melanin pigment granules (M.P.) are quite numerous in the cytoplasm. Co, Collagen fibre; Ax, unmyelinated axons. At the tip of the right hand side is a nucleus of a Schwann cell (Sch. Nu). ( $\times 9,000$ .)

None of our pinealectomized hamsters with tumours survived for more than 38 days after inoculation. It is difficult to draw any conclusions from this small group of hamsters, especially because all these tumours had ulceration, necrosis and consequent massive infection. Fortner *et al.*<sup>13</sup> have reported a host survival time varying from 34 to 82 days after inoculation of this tumour. They also reported that there was always a high incidence of lung metastases and evidence of other visceral metastases from this tumour at the time of death of these animals. But the remarkable rapidity of metastatic spread observed in this experiment after pinealectomy was not observed on any occasion by Fortner *et al.*<sup>13</sup> and was corroborated by our two sets of controls.

The data obtained from this investigation tend to support a concept that the pineal body exerts some control on the growth and spread of pigmented neoplasms in hamsters. These experiments, however, do not explain whether the control is mediated by way of a pineal hormone which acts on melanophores or whether ablation of pineal *per se* depresses host resistance to tumours and homografts. Further experiments dealing with non-pigmented tumours in albino rats are at the moment in progress in order to elaborate these points.

We thank Professor R. Warwick for his help in the preparation of this report.

### Induction of Amyloidosis by Cadmium

AMYLOIDOSIS has been produced in experimental animals by injecting a variety of substances, most of them proteinaceous<sup>1</sup>. We have found that a simple chemical, cadmium, given to rabbits as cadmium chloride in relatively small doses over a long period of time will produce a severe form of amyloidosis.

The dosage chosen was one which had been found by Kench<sup>2</sup> to produce a proteinuria in rabbits similar to that found in humans after prolonged exposure to cadmium. New Zealand outbred rabbits were injected with cadmium chloride in a dose of 1 mg/kg/day, 5 days a week. Two injection schedules were used. The first group of three animals received cadmium for an 8 week period. They were rested for 10 weeks and then reinjected for 4 weeks. They received an average total dose of 224 mg of cadmium chloride (68 mg/kg). They were killed at the end of the second injection period (22 weeks after the first injection). The second group of three animals received the cadmium for 9 weeks. One animal died of unknown causes after 6 weeks. The two that survived received an average total dose of 127 mg of cadmium chloride (47 mg/kg). They were biopsied 20 weeks after completion of the injections (30 weeks after the first injection) and were killed for complete autopsies 60 weeks after the first injection.

Fig. 1. *a*, Glomerulus in renal tissue obtained 30 weeks after cadmium treatment was begun, showing the amorphous amyloid occupying most of the glomerular tuft. Congo red ( $\times$  c. 260). *b*, Polarized light micrograph of the same glomerulus as in Fig. 1, showing the birefringence of amyloid stained with Congo red ( $\times$  c. 260).

The tissue obtained at biopsy or autopsy was processed both for light and for electron microscopy. Sections stained with Congo red were also examined by polarized light and fluorescence microscopy to detect the characteristic birefringence and fluorescence of amyloid stained with Congo red. Thin sections were examined in the electron microscope to detect the fibrils characteristic of amyloid in tissue<sup>1</sup>.

Histological examination revealed a small amount of amyloid in the glomeruli of animals killed at 22 weeks. The deposits involved about 10 per cent of each glomerulus. Far more amyloid was seen in the kidneys of the animals biopsied at 30 weeks, although these animals had received a smaller dose of cadmium, and autopsy of the same animals at 60 weeks revealed massive involvement of the kidney with amyloid; almost every part of each glomerulus was replaced by material which had features characteristic of amyloid. Fig. 1*a* shows a severely affected glomerulus in the tissue obtained at 30 weeks, stained by the Congo red technique. Fig. 1*b* shows the same glomerulus examined with polarized light, and showing the birefringence which is so typical of amyloid stained with Congo red. The identity of this material as amyloid was also established by electron microscopy. In addition to renal involvement, the animals killed at 60 weeks also showed extensive infiltrates in the spleen and the liver.

People who work with cadmium develop renal tubular lesions<sup>3</sup> and similar lesions have been found in rabbits<sup>4</sup> and rats<sup>5</sup> injected with cadmium. Amyloidosis has not, however, been described previously either in man or in animals with cadmium poisoning. Few of the animal studies have been carried out for a period as long as that reported here, and the failure of earlier workers to find this lesion may be due to the fact that the animals were not kept alive long enough to develop amyloidosis. The absence of amyloidosis in men who have been exposed for periods up to 15 years does, however, suggest that species differences in the susceptibility to cadmium may also be present.

## PHYSIOLOGY

## Phagocytosis by Synovial Cells

THE ability of synovial cells to phagocytose small particulate matter has long been accepted for haemosiderin and can be readily demonstrated in such cells in ordinary histological sections from cases of chronic haemarthrosis<sup>1</sup>. Only now is the full phagocytic power of the synovial cell

Fig. 1. Synovial cells (S) with phagocytosed erythrocyte (E) ( $\times 10,000$ ).

Fig. 2. Synovial cell phagocytosing "fibrinoid" material and a cell fragment. "Fibrinoid" material is seen lying free in joint space at A, and embraced by a filopodium at B. Similar material can be seen in phagosomes at C. A cell fragment surrounded by filopodia is seen at D ( $\times 19,500$ ).

beginning to be recognized. Thus, it has been shown that not only a variety of small particulate substances like ferritin<sup>2</sup>, gold<sup>3</sup>, thorotrast<sup>4</sup>, iron dextran<sup>5</sup> and carbon<sup>6</sup> when injected into the joint space are readily taken up by these cells but that entire erythrocytes<sup>7</sup> can also be ingested in this fashion (Fig. 1). This is indeed remarkable because usually erythrocytes are fragmented before phagocytosis by macrophages<sup>8</sup>.

During the course of our investigations of the ultrastructure of rheumatoid synovium we have collected further evidence about the phagocytic potentials of the synovium. In this condition cellular debris and "fibrinoid" material are frequently found in the joint space, and this is rapidly phagocytosed by the synovial cells. Fig. 2 shows some "fibrinoid" material lying in the joint space at A. This material can also be seen trapped between the cell wall and a filopodium at B. Furthermore, morphologically similar material can be demonstrated within the cell, usually in single membrane bound bodies (C). These appearances are compatible with the idea that "fibrinoid" material is being phagocytosed and incorporated into the synovial cell to form phagosomes. Phagocytosis of a cell fragment containing what appears to be a lipid droplet and four lysosomal bodies is seen at D.

Thus it is now evident that the synovial cell can phagocytose a large variety of small and large particles and that its phagocytic powers match and in some instances perhaps even excel that of the macrophage, the classical scavenger which plays a fundamental part in the removal of particulate debris in various pathological states.

## Influence of Sleep Deprivation on Iron Metabolism

AMONG the basic factors which have a bearing on iron metabolism and its serum level certain attention has been paid during the past two decades to the influence of biological rhythms<sup>1</sup> and various stressing stimuli<sup>2</sup>. In conjunction with this we decided to make use of an experimental set-up which involves the prolonged and complete upset of the basic biological rhythm of the alternation of wakefulness and sleep—that is, sleep deprivation. This work was stimulated in particular by the finding of an extreme drop of plasma iron (revealed in preliminary experiments) during the 120th hour of vigilance in four experimental subjects<sup>3</sup>.

The level of plasma iron was investigated daily in six men and two women<sup>4</sup>, the total serum binding capacity for iron in four<sup>5</sup> and in all subjects the urinary iron excretion<sup>6</sup>. Blood specimens were collected between 7 and 8 a.m. during the control period before the experiment, then during five days of sleep deprivation and then during the recovery period. In the women the iron absorption from the digestive tract in serum was investigated after administration of six tablets of 'Feronat C'<sup>\*</sup>. Because the plasma iron level may be influenced by the administered preparation, however, the two above mentioned experi-

\* One tablet of 'Feronat C' Spofa contains 200 mg ferrum gluconicum and 20 mg ascorbic acid, that is, 1 tablet = 22 mg ferrous iron.

mental subjects were not included in the final evaluation, though their curves of sideraemia on fasting were on the whole similar as in the other experimental subjects. In four men the investigation was supplemented by ferrokinetics using  $^{59}\text{Fe}$ . Simultaneously, the complete haemogram was examined as well as the plasma volume and the glucose-6-phosphate dehydrogenase activity in red blood cells.

The plasma iron levels in six subjects before the experiment were balanced and within a normal range (Table 1). During sleep deprivation there was a gradual decline, the maximum drop being to half the original levels. The decline was most marked during the first 48 h of sleep deprivation, and was much slower during the subsequent intervals. The return to normal values, during the second control period after the end of the experiment, was slow and took roughly one week.

The total binding capacity of serum for iron, that is, the binding capacity of transferrin, declined much less and the maximum drop was during the seventy-second hour of vigilance (Table 2). On subsequent days it oscillated only slightly and there was no further decline. The return to normal was slow.

For the evaluation of the observed changes it is important to present the results of other examinations. First of all the participation of the renal factor can be eliminated because the urinary iron excretion does not change in the course of the experiment. Absorption does not show any detectable changes; the shape of the absorption curves on the first day and after 96 h of the experiment in the two experimental subjects is identical. Later determinations of the haemoglobin level and the number of reticulocytes ruled out anaemia caused by the withdrawal of blood specimens as the source of the observed changes. The investigation of ferrokinetics with  $^{59}\text{Fe}$  indicate that the half-time of the removal from plasma ( $T/2$ ) is in all four subjects within a normal range (normal values are 60–120 min, in our subjects 75–105 min). The absence of a more marked shortening of the half time of the clearance of  $^{59}\text{Fe}$  does not rule out the possibility that this experiment with the ferrokinetics which was started at the time of the assumed marked drop of sideraemia, that is, during the fourth-eighth hour, did not record the time of the rapid removal. The increased utilization of the removed iron by red cells is striking (100 per cent in all instances). This emphasizes the dominant position of erythropoiesis in iron metabolism. The slightly reduced iron supply is offset by enhanced utilization. The other indicators of erythropoiesis, the erythropoietic index and the relative erythropoietic activity are at the upper borderline of normal values. Assessment of activity did not reveal an enhanced deposition in tissues. The unaltered activity of glucose-6-phosphate dehydrogenase seems to confirm the view that in the investigated interval of protracted wakefulness no marked changes in erythropoiesis took place. The drop of the iron level is probably connected with increased removal into the reticulohistiocyte system.

The interpretation of mechanisms and causes of the observed changes is very complicated. Serious disorders of neurogenic and endocrine regulatory mechanisms participate in the genesis of the drop in the level of serum iron during sleep deprivation<sup>3</sup>. This is suggested in particular by the abnormal results of a number of psychological tests and the altered activity of the central sympathetic in the mecholyl test<sup>7</sup>, the increased excretion of vanillyl-mandelic acid, 17-OH steroids in urine<sup>8</sup>, the striking leucocytosis and eosinophilia.

## A Neurosecretory Tissue in Octopus

IN view of the amount of information available about the structure of the nervous system in cephalopod molluscs, there is surprisingly little known about their neurosecretory systems. The epistellar body, associated with the stellar ganglion, was thought to be a neurosecretory organ<sup>1</sup>, but it is now known to have the structure of a photoreceptor<sup>2</sup>. Several other structures of unknown function have also been described that may have a neurosecretory function<sup>3,4</sup>. The only organ that has been shown to have an endocrine function in cephalopods is the optic gland of *Octopus*; behavioural studies show that it controls maturation of the gonads and hence sexual maturity<sup>5</sup>. A preliminary report on the fine structure of this organ gave little information of any granular content of the cells<sup>6</sup>. A group of possible neurosecretory tissues that have a similar histological structure have recently been described—the vena caval tissue, associated with the vena cava in *Eledone cirrosa*, *Octopus vulgaris* and *Sepia officinalis*<sup>7,8</sup>, and the juxta-ganglionic tissue, associated with the inferior buccal ganglia and buccal sinus in *Octopus vulgaris*<sup>9,10</sup>. The juxta-ganglionic tissue, first described by Bogoraz and Cazal<sup>9</sup>, consists of a group of small

nerve cells lying outside, but associated with, the inferior buccal ganglia (see ref. 10 for diagram of its position). These cells give rise to axons that pass down to the buccal sinus and end on its surface as a tangled mass of interweaving fibres<sup>10</sup>.

The inferior buccal ganglia of *Octopus vulgaris* together with associated juxta-ganglionic tissue were dissected out and fixed for electron microscopy with 1 per cent osmium tetroxide (buffered with veronal acetate to pH 7.3), stained with phosphotungstic acid, dehydrated in graded ethanols, and embedded in 'Araldite'<sup>11</sup>. When sections are viewed with the electron microscope the axons of the secretory cells can be seen to end by direct apposition on to the basement membrane of the sinus vessel. There are no pericytes on the outside of the basement membrane, unlike all other cephalopod vessels so far studied<sup>11</sup>. There is, however, a discontinuous layer of endothelial cells on the inside of the basement membrane. The basement membrane is particularly obvious because of the phosphotungstic acid staining. The neurons and axons are filled with membrane-bound, electron-dense granules of some 1000–2000 Å in diameter (Fig. 1). This type of granule is typical of that found in neurosecretory tissues of a variety of animals<sup>12–14</sup>. As well as these large granules some smaller vesicles that are not electron-dense are present and these have a diameter of some 500 Å. Some profiles contain mainly or solely these smaller vesicles. This variety of vesicles is reminiscent of the arrangement in the vertebrate neurohypophysis<sup>12,15,16</sup>. It seems likely that these small vesicles are associated with or derived from the larger electron-dense ones<sup>16</sup>. Other suggestions have been made<sup>15</sup>, including the possibility that they may be typical synaptic vesicles, containing acetyl choline<sup>17</sup>, and be involved with the release of the larger electron-dense granules.

The position of the axonal endings of the nerve cells and their content of numerous electron-dense granules of a typical neurosecretory sort makes it likely that the juxta-ganglionic tissue has a neurosecretory function. Studies using other techniques would be needed to confirm this. It would be interesting to examine the vena caval tissue<sup>7,8</sup>, and other similar tissue found in the brain of certain decapod cephalopods<sup>18</sup>, to see whether similar "neurosecretory granules" were present.

Fig. 1. An electron micrograph of axons (ax) of the juxta-ganglionic tissue ending on the basement membrane (bm) of the buccal sinus (bs). Note the electron-dense granules (g) commonly present in the axons and the less common clear vesicles (v) that are also present. e, Endothelial cell. (Fixed osmium, buffered veronal acetate, stained phosphotungstic acid.)

### Zinc Concentrations of Fast and Slow Contracting Muscles in the Lobster

DURING an investigation of the regulation of zinc in the lobster *Homarus vulgaris* it was found that different skeletal muscles may contain very different amounts of zinc. The main flexor muscle from the abdomen contains 14.4 µg/g, but pooled samples of the extensor and flexor muscles of the coxopodite segments of the walking legs contain 60 µg/g<sup>1</sup>. Analyses of muscle samples in other decapod crustaceans have suggested that a low concentration of zinc is characteristic of muscles which can contract quickly. To confirm this I compared muscles with certain structural differences which suggest that their modes of functioning are different.

Alexandrowicz has noticed that some of the components of the dorsal musculature in crustaceans have a coarse and others a fine cross-striation<sup>2,3</sup>, and suggested that they may form two systems, one for slow and the other for fast contractions<sup>4</sup>. These muscles appeared, therefore, to possess the above requirements. The superficial and deep extensors and flexors of the abdomen and the three dorsal thoraco-abdominal muscles of the lobster were used for analysis. (For the situation and nomenclature of the latter muscles see ref. 3). The characteristics of the muscles and their concentrations of zinc are shown in Table 1.

The supposition that the coarse and fine striated muscles differ in their mode of contraction has since been confirmed by experimental demonstration of the presence of slow and fast systems in both the dorsal and ventral musculature of the decapod crustacea<sup>5,6</sup>.

Results of analyses of zinc from three different lobsters in Table 1 support the original idea that fast muscles contain less zinc than slow ones. The slow muscles contain five to seven times as much zinc as the fast muscles and twice as much zinc as any other lobster tissue (see ref. 1). Previous results have suggested that the

Muscle	Table 1		Zinc (µg/g)		Mean
	Cross striation	Mode of contraction			
First and second dorsal thoraco-abdominal	Coarse	Slow	103	100	—
Third dorsal thoraco-abdominal	Fine	Fast	21	19	—
Superficial abdominal extensor	Coarse	Slow	73	107	99
Deep abdominal extensor	Fine	Fast	15	15	15
Superficial abdominal flexor	Coarse	Slow	111	83	120
Deep (main) abdominal flexor	Fine	Fast	15	17	13
Whole blood	—	—	5.2	6.6	6.9

Table 2

Time for which zinc-65 absorbed (days)	Muscle	Muscle/Blood ratio	
		Zinc-65	Stable zinc
12	First and second dorsal thoraco-abdominal	0.62	12.1
12	Third dorsal thoraco-abdominal	0.27	2.3
30	Superficial abdominal extensor	0.89	14.4
30	Deep abdominal extensor	0.50	2.2
30	Superficial abdominal flexor	1.05	17.3
30	Deep (main) abdominal flexor	0.41	2.0

permeability of the main flexor muscle of the lobster to zinc is low, because virtually no increase in its concentration of zinc occurred when the amount of zinc in the blood was raised by a factor of six<sup>1</sup>. In the present work no specific attempt has been made to measure the permeability of these muscles to zinc. An indication of the permeabilities of slow and fast muscles, however, was obtained by measuring their concentrations of zinc-65 in lobsters which had been kept in sea water to which the isotope was added. These results are summarized in Table 2. The concentrations of zinc-65 are expressed as muscle/blood ratios and are compared with the corresponding stable zinc ratios.

Muscle/blood ratios for zinc-65 in slow muscle are roughly double those for fast muscle which suggests that slow muscle is more permeable to zinc. The stable zinc ratio for slow muscle is much higher than that for fast muscle, and so it will presumably take longer for the zinc-65 ratio for slow muscle to approach that for stable zinc.

The nature of the difference in concentration of zinc between the two types of muscle is not known, but might be related to differences in enzyme content. Enzymes such as lactic and glutamic dehydrogenase<sup>7</sup> and carbonic anhydrase<sup>8</sup> have been detected in crustacean muscles. In vertebrates these have been shown to be zinc-metallo-enzymes<sup>9,10</sup>. Other vertebrate muscle enzymes, for example ATPase, have been shown to be activated by low concentrations of zinc<sup>11</sup>. It was thought at one time that zinc takes part in the function of the relaxing factor in vertebrate muscle<sup>12</sup>, but this now seems to have been disproved<sup>11</sup>.

In the lobster, and presumably in other decapod crustaceans, the difference between the concentrations of zinc of fast and slow abdominal muscles is a feature which should make them suitable material for determining the role of zinc in crustacean muscle.

## Calcium and Contraction of Heart and Smooth Muscle

It is well established that an increase in the intracellular concentration of ionized calcium after excitation in the membrane is the key factor for initiation of contraction of various types of muscles. In skeletal muscle the tubular structure within the muscle fibres which is in connexion with the surface membrane, the endoplasmic reticulum, has been considered by many to serve as a supply source of this ionized calcium. For heart and smooth muscles, however, in which the development of this structure has

been found to be rather poor, there is still uncertainty as to whether the calcium comes from outside the muscle. We have attempted to elucidate this point, using calcium buffers.

Experiments were carried out on the isolated taenia coli of the guinea-pig and on the ventricular strip of *Rana catesbiana*. To obtain information about mammalian heart muscle, the right ventricular strip preparation described by Feigen *et al.*<sup>1</sup> was used in some experiments. All the experiments were carried out in winter-time, from December to March. The muscle preparations were suspended in a 5 ml. organ bath, immersed in water at  $20 \pm 0.3^\circ \text{C}$  for frog and  $36 \pm 0.3^\circ \text{C}$  for mammalian muscle. The bathing solution had the composition of conventional Ringer or Ringer-Locke solution, except that sodium bicarbonate was replaced by *tris*-maleate buffer ( $\text{pH} = 7.1$ ,  $5.0 \text{ mmolar}$ ). The solution was aerated with 100 per cent oxygen. To prepare solutions with low stabilized concentrations of free ionized calcium, 5 mmoles of ethylene glycol *bis*( $\beta$ -aminoethyl ether)-*N,N'*-tetraacetic acid (EGTA) was used as a chelating agent. In the  $\text{pH}$  range  $4.0$ – $7.5$  the ligand exists mainly with two negative charges and the concentrations of ionized calcium can be calculated sufficiently accurately from the equation

$$p[\text{Ca}^{++}] = 2 \text{pH} - 7.28 + \log \left\{ \frac{[\text{EGTA}] \text{ added}}{[\text{CaCl}_2] \text{ added}} - 1 \right\}$$

As a model of the contractile response of these muscles, potassium contracture (K-contracture) was adopted, which was produced by isotonic potassium sulphate Ringer or isotonic potassium sulphate Ringer-Locke solution. The contracture tension developed was recorded on a self-balancing potentiometric recorder with the aid of a strain-gauge transducer and a d.c. amplifier. The membrane potential of taenia coli was recorded by the sucrose-gap technique.

Fig. 1 shows that K-contracture in the taenia coli consisted of the initial rapid rise of tension followed by a phase of sustained contraction, which lasted as long as

Fig. 1. Effect of the concentration of external calcium on the shape of K-contracture of guinea-pig taenia coli. Potassium contracture (K-contracture) was induced by potassium sulphate-Locke solution. Contracture tension was recorded isometrically with a strain-gauge transducer on a self-balancing potentiometric recorder. Low stabilized concentration of calcium (expressed in moles in the figure) was produced by adding 5 mmoles of EGTA. The final levels of the tonic phase in  $10^{-7}$  and  $10^{-8}$  molar calcium medium were similar and cannot be differentiated in this figure. The upper curve represents the initial phasic response in  $10^{-7}$  molar calcium and the lower that in  $10^{-8}$  molar calcium. Note the inhibition of the initial phasic portion in low calcium.

there was a large concentration of potassium in the bathing medium. In contrast, the contractile response in the frog's heart proceeded more slowly to reach a peak in more than 1 min and then declined to a phase of maintained contraction (Fig. 2). In Fig. 2 only the response of the frog's heart is depicted, for, although the response was faster, its shape in the rat heart was essentially the same. These figures show that when the concentration of the free ionized calcium in the bathing medium was reduced by addition of EGTA a diminution of the contractile response was observed both in heart and smooth muscle. In taenia coli, however, the initial quick phasic response was preferentially affected by this procedure and it finally disappeared completely when the concentration was reduced below  $10^{-7}$  molar, while the ensuing tonic portion persisted even at a concentration of  $10^{-8}$  molar or less of calcium (Fig. 1). In heart muscle of frog or rat, the contractile response to isotonic potassium sulphate was, in contrast, uniformly affected over its full time course, and at calcium concentrations below  $10^{-7}$  molar no contractile response could be elicited; the muscle actually relaxed instead (Fig. 2).

Fig. 2. Calcium and K-contracture in heart muscle of *Rana catesbiana*. Note the reversal of the response in  $5 \times 10^{-8}$  molar calcium.

Fig. 3. Effect of concentration of external calcium on the membrane potential change during K-contracture. Guinea-pig taenia coli. Upper two curves: contracture tension and membrane potential in 2.2 mmolar calcium medium. Membrane potential was recorded using the sucrose-gap technique. Lower two curves: same as in the upper, but in  $10^{-8}$  molar calcium medium.

According to recent work<sup>2-5</sup> on rabbit myofibrils, purified actomyosin of rabbits, glycerinated skeletal and smooth muscle of the hog and the intact leg muscle of a crab the threshold concentration of free ionized calcium for the activation of these contractile systems is  $10^{-6}$ – $10^{-7}$  molar. Taking this figure into consideration, it may be concluded from the present data that contraction of heart muscle is initiated and maintained solely by a diffusion of calcium from the surrounding medium into the muscle fibres. Part of the tonic phase as well as the initial phasic portion of K-contracture of taenia coli could be viewed in the same way. But to explain the portion of the tonic phase that persisted even at a concentration of  $10^{-8}$  molar of calcium we must assume, in addition, the existence of some binding site for calcium within the muscle fibres, from which calcium is released little by little into the interior influenced by the sustained membrane depolarization, thereby producing a tonic phase of contracture. Thus, the smooth muscle fibre has two different means by which it can raise the intracellular concentration of free ionized calcium, in contrast to heart muscle, which depends entirely on the surrounding medium for supply of the necessary calcium. For comparison, we have investigated sartorius and rectus abdominis of *Rana catesbiana*; K-contracture in these muscles was often elicitable even when the extracellular calcium concentration was reduced to  $10^{-7}$  molar or less, in good agreement with the well known efficient calcium-binding capability of the vesicular relaxing factor of skeletal muscle.

The free ionized calcium entering into the muscle fibres during the initial phasic portion of the K-contracture of taenia coli could be identical with that calcium which possibly constitutes the spike potential of this muscle, for a reduction of the concentration of extracellular calcium to below  $10^{-8}$  molar invariably resulted in a complete extinction of the spike discharge seen superimposed on the rising phase of membrane depolarization of control preparations, in association with the complete abolition of the initial phasic portion of the contractile response (Fig. 3).

## BIOPHYSICS

### Existence of Collective-excitation Energy Losses from an Electron Beam passing through Biological Materials

In radiobiology, the transfer of energy from ionizing radiation to an absorber is often expressed in terms of the mean energy transferred per primary ionization and the number of such ionizations/g of absorber. Recently, Rauth and Hutchinson<sup>1</sup>, using an electron beam spectrometer with an energy resolution of about 1 eV, have directly measured the energy losses from an electron beam passing through thin organic films ('Formvar' and polystyrene). Very few electrons were observed to have lost energy amounts of less than 10–12 eV and the most probable energy loss was about 25 eV. For electron beams of energies of between 5 and 20 keV, the mean energy lost per primary ionization was found to be  $60 \pm 10$  eV. This value is considerably less than that of 100 eV (ref. 2)

estimated from data on gases and from calculations by Bethe<sup>3</sup>.

The difference between these two values may result from the existence in solids of energy-loss processes which do not occur for gases. Collective excitation of valency electrons is one possible mechanism. Collective energy losses as observed in metals have been explained in terms of the plasma model of Bohm and Pines<sup>4</sup>, in which discrete amounts of energy, in the region of 10–20 eV, are lost in the excitation of longitudinal oscillations in the free-electron plasma. Multiple events of this type give rise to a number of peaks in the energy-loss spectrum of a metal foil. Birkhoff<sup>5</sup> has shown that for aluminium about 16 per cent of the energy dissipated goes to plasma excitation.

The plasma model is somewhat unrealistic for semi-conductors and insulators in which characteristic energy losses, thought to be due to similar collective excitations, are also observed (ref. 6 and our unpublished work). Fano has recently attempted to formulate a theoretical model in which excitation of a cubic lattice of coupled dipole oscillators is proposed as an alternative to the plasma model. Simpson<sup>7</sup> has pointed out that it is not necessary to restrict the plasma model to free electrons in metals, because the plasma frequencies are so high that the electron displacement is only about 1 Å. Collective oscillations in the valence electrons of non-metals may therefore occur.

Whatever the outcome of such theories, it is fairly clear that collective excitations are a possible mode of energy loss in organic materials and that data obtained for gases may not be directly carried over to the condensed state. It is important therefore to know if such processes occur in biological materials.

In order to test this possibility, a high-energy electron beam spectrometer (recently constructed at the University of Reading) with an angular resolution of  $10^{-4}$  radians and an energy resolution of 1 eV has been used to investigate the energy losses in thin films of calf thymus nucleic acid (supplied by British Drug Houses, Ltd.). This instrument has been described elsewhere<sup>8</sup>.

Self-supporting films approximately 2000 Å thick were produced by allowing 0.002 ml. drops of nucleic acid solution (0.05 per cent w/v sodium salt in distilled water) to dry on 3 mm diameter electron microscope specimen grids.

Energy-loss electrons scattered at small angles to a well collimated 150 keV electron beam passing through a film were analysed by a  $180^\circ$  magnetic spectrometer, using direct electronic recording techniques. Fast recording times (5–15 sec) and low beam currents ( $10^{-7}$  amp/cm<sup>2</sup>) were used to minimize radiation damage to the specimen. Electron diffraction photographs from such specimens showed a strong ring at a diameter corresponding to a spacing of 2.7 Å. This ring was absent in specimens which had suffered considerable radiation damage, in which event a more diffuse pattern similar to that obtained from carbon specimens was observed. The ring at 2.7 Å presumably arises from the existence of hydrogen bonds, with spacings in the region of 2.7 Å, in the undamaged nucleic acid specimens.

As a result of the long-range nature of the interactions which correspond to collective excitations, the transfer of momentum from the incident electron is small and electrons losing discrete amounts of energy by such interactions are scattered through very small angles. Ferrel<sup>9</sup> has given the differential scattering cross-section as approximately

$$\sigma(\theta) = \theta_E / (2\pi a_0 (\theta_E^2 + \theta^2)) \quad (1)$$

where  $a_0$  is the Bohr radius ( $5.3 \times 10^{-9}$  cm) and  $\theta_E = \Delta E / 2E$  ( $\Delta E$  is the energy loss and  $E$  the incident beam energy).

For  $E = 150$  keV and  $\Delta E = 25$  eV,  $\theta_E$  is  $0.83 \times 10^{-4}$  radians and this also corresponds to the scattering angle at which the intensity is just half the intensity at  $\theta = 0$

(from equation (1)). The majority of the scattering is therefore within a cone of semi-vertical angle  $10^{-3}$  radians. Electrons having suffered two 25 eV losses will have a broader distribution of lower intensity.

From the foregoing details it is seen that collective excitation losses are characterized by discrete peaks in the energy-loss spectra of electrons transmitted through thin specimens, and measured at angles within about  $10^{-3}$  radians to the incident beam direction. At angles of about  $10^{-4}$  radians for thin films, the single loss process is most probable, whereas for larger angles the double loss or higher multiple loss processes become relatively more probable, although at angles greater than  $10^{-3}$  radians the intensity is very low.

These characteristics are clearly seen in the energy-loss spectra from a 2000 Å thick film of nucleic acid which are reproduced in Fig. 1. The peak at 50 eV, although barely visible at  $2.5 \times 10^{-4}$  radians, becomes very prominent at a scattering angle of  $10^{-3}$  radians (note the change of vertical scale for the spectra at different scattering angles).

Fig. 1. Energy-loss spectra from a 150 keV beam of electrons passing through a thin film of nucleic acid.  $\theta$  is the scattering angle.

This evidence supports recent suggestions that collective losses exist and are important in radiobiology<sup>10</sup>. The lifetime of the collective excitation states is of the order of  $10^{-16}$  sec and, although the nature of the decay process is not fully understood, there is the possibility that the energy is finally dissipated in the rupture of a number of chemical bonds over a region much larger than that associated with the ion cluster. This could significantly affect determinations of radiation sensitive volumes by the associated volume method due to Lea<sup>11</sup>.

This work has formed part of an investigation of electron scattering at high energies, which is being carried out with

the support of the Royal Society and the Science Research Council, whom we thank.

## BIOLOGY

### Blood Borne Factors in Circadian Rhythms of Activity

RHYTHMS of a circadian nature in locomotor and other kinds of activity have been described in a variety of organisms. While much is known about the time course and phase relations of such rhythms, very little is known about the internal regulating mechanisms. The diurnal locomotor rhythm in the cockroach is controlled by neurosecretory cells located in the sub-oesophageal ganglion<sup>1,2</sup>. Transplantation experiments have shown the importance of the presence of the sub-oesophageal neurosecretory apparatus for the persistence of the locomotory rhythm, but no variations with the time of the day in the direct effects of the neurosecretory products on the degree of activity of the central nervous system have been demonstrated.

It was earlier demonstrated<sup>3</sup> that the isolated ventral nerve cord of the scorpion exhibits "spontaneous" electrical activity. The level of such activity was shown to vary with the time of the day, the maximum activity being noticed between about 4 p.m. and 12 midnight with peak activity around 8 p.m. From about 11 p.m. there was a decrease in activity; activity almost stopped in the early hours of the morning. The scorpion exhibits a diurnal rhythm in its locomotory activity and the time course of this locomotory rhythm is the same as that of the above-mentioned rhythm in the electrical activity of the ventral nerve cord. It therefore seems very likely that the locomotory rhythm flows from the rhythm of activity in the central nervous system. In view of this possibility it would be of particular interest to know the factor or factors that modulate the activity of the nervous system.

In view of the known effects of neurohormones on the spontaneous activity of the central nervous system<sup>4-7</sup> and the rhythm in the secretory activity of certain groups of neurosecretory cells in the sub-oesophageal ganglion of the scorpion<sup>8,9</sup>, the effects of blood and of extracts of the cephalothoracic nerve mass on the activity of the ventral nerve cord at different times of the day are of interest. Well fed scorpions, *Heterometrus fulvipes*, kept in the laboratory in conditions of normal day and night, were used in the present investigation. Blood (haemolymph) and the cephalothoracic nerve mass were taken from these scorpions at 12 noon, 5 p.m., 11 p.m. and 2 a.m. For this purpose two scorpions were taken into a cold room at the required time and first the blood was drawn from them with a hypodermic syringe at the joint of the "hand" of

the pedipalp with the proximal podomere. Blood drawn from two individuals at the same time was pooled together and immediately placed in the ice-box of the refrigerator at  $-5.0^{\circ}\text{C}$ . At all times of the day the quantity of blood that could be drawn was about the same and usually 0.4–0.5 ml. of blood was drawn from each animal. No anticoagulant was used, because clotting is not effective in this animal at such low temperatures. These scorpions were dissected immediately to remove the cephalothoracic nerve mass which is taken out quickly, from each of the two animals, into a glass homogenizer kept at  $0^{\circ}\text{C}$  in an ice-bath. A homogenate was prepared in sterilized cold ( $0^{\circ}\text{C}$ ) scorpion Ringer and this was extracted and centrifuged and the supernatant was stored at  $-5.0^{\circ}\text{C}$  until further use. No extract or blood was stored longer than 20 h before it was used.

To investigate the effects of the blood and extracts of cephalothoracic nerve mass thus prepared at different times of the day on the "spontaneous" activity of the isolated ventral nerve cord, the following procedure was carried out. The ventral nerve cord of the normal animal was exposed (always between 8 a.m. and 10 a.m. when the natural activity of the cord is minimal) from the dorsal side and was isolated by severing all the segmental nerves. A chain of four ganglia, consisting of the three mesosomatic and the first metasomatic ganglia, was isolated by severing the cord anteriorly and posteriorly, and this isolated preparation was used for recording. The recording electrodes (bipolar silver/silver chloride) were placed between the first and second mesothoracic ganglia and the electrical activity was recorded using conventional electrophysiological equipment. The photographic records were used for visual pulse height analysis.

The sequence of each set of recordings was as follows: first the spontaneous activity was recorded after prolonged (more than 15 min) bathing in the perfusion fluid (scorpion Ringer); then the Ringer solution was replaced by the required extract of cephalothoracic nerve mass or the blood and the activity was recorded at intervals of 5 min for 15 or 20 min; finally the test solution was replaced by the Ringer solution and the activity was again recorded after repeatedly washing the cord with the perfusion fluid. Thus recordings were made using blood and extracts of cephalothoracic nerve mass obtained at different times of the day indicated above. For recording, the electrodes with the nerve cord on them were lifted, just above the perfusion fluid, into the air.

The analysis of the records (Table 1) shows that there is a great increase in the spike activity when either the blood or the extract of cephalothoracic nerve mass from the 5 p.m. scorpions is applied to the isolated ventral nerve cord. This increase was not only caused by the increased frequency of the "normally" active small units but also by the recruitment of new units, especially the large "giant" units which have been reported to be active during the evening. The response is maintained as long as the nerve cord is bathed in perfusion fluid containing the active substance. On an average the activity increases by 34 per cent more than the control values obtained in scorpion Ringer. Similar increase in activity is obtained with the 8 p.m. blood and extract of cephalothoracic nerve mass. On the other hand, an opposite effect is noticed when blood or the extract obtained from either the 11 p.m. or the 2 a.m. scorpions is applied. The greatest depression in the activity of the nerve cord is noticed with the application of the 2 a.m. extract; there is a 60 per cent drop in the spike activity compared with the control values in Ringer solution. Both the blood and the extract of cephalothoracic nerve mass obtained from the 12 noon scorpions have little or no effect on the spontaneous electrical activity of the nerve cord.

From the results obtained it is clear that the effects of the blood and extract of cephalothoracic nerve mass on the spontaneous electrical activity of ventral nerve cord are not always the same. The time of the day when the

Table 1. EFFECT OF EXTRACT OF CEPHALOTHORACIC NERVE MASS AND BLOOD ON THE ELECTRICAL ACTIVITY OF THE ISOLATED VENTRAL NERVE CORD OF THE

Time of day: 5 p.m.			8 p.m.			SCORPION 11 p.m.			2 a.m.			12 noon

Values are spikes/10 sec. Data from six test animals are pooled. Each animal was tested with the extract and then with blood pooled from two donor animals killed at the times shown, alternating with the Ringer test. Tests on the extract and blood from all five testing times were carried out consecutively in one session of 2-2.5 h on the ventral nerve cord of test animals; therefore, ten experimental tests alternating with ten Ringer tests were carried out. Each test lasted 5-15 min during which ten to fifteen 10 sec samples were averaged. No trend was seen over the 15 min of a given test or in Ringer over the 2-5 h of a session.

blood and the extracts are obtained from the animal seems to be important. Two types of effect are seen. Extracts obtained from the 5 p.m. and 8 p.m. scorpions excite and increase the electrical activity, but those obtained at 11 p.m. and 2 a.m. inhibit and diminish the electrical activity. Both the excitatory and inhibitory effects are obtained whether the blood or the extract are used. From these results it may seem that the 5 p.m. and 8 p.m. blood as well as extract of cephalothoracic nerve mass contains some substance which excites nerve activity while a substance inhibiting nerve activity might be present in the 11 p.m. and 2 a.m. blood and extract of cephalothoracic nerve mass.

Although we do not know the nature of these excitatory and inhibitory principles, it is possible that they are of the nature of neurohormones which are produced by the neurosecretory cells in the sub-oesophageal ganglion and released into the blood. This possibility is strengthened by the recent demonstration<sup>7</sup> of the occurrence of two separate neurohormones in the brain and corpora cardiaca of the cockroach, one (neurohormone  $D_1$ ) capable of evoking hyperautorhythmia in the central nervous system and the other (neurohormone  $C_1$ ) capable of inhibiting the existing electrical activity in the ganglia. In view of the already demonstrated rhythmic variations in the activity of neurosecretory cells in the scorpion<sup>8</sup>, it is very likely that two neurohormones, one excitatory and the other inhibitory, are produced out of phase with each other by the neurosecretory cells, and released at different times into the blood. Thus, the accumulation and release of these two antagonistic neurohumoral principles can modulate the spontaneous electrical activity of the central nervous system into a circadian rhythm, with an active phase from about 4 p.m. to 11 p.m. and an inactive (or less active) period from about midnight to the next afternoon. This can be achieved if the activating neurohormone is released into the blood from about 4 p.m. till about 10 or 11 p.m. and thereafter while the release of the activating substances stops, the inhibitory neurohormone is released into the blood from about 11 p.m. onwards. Perhaps around 12 noon the two substances antagonize each other equally.

This modulation of the electrical activity in the central nervous system is of great behavioural significance because it may form the basis for the regulation of the circadian locomotory rhythm with the same time course, known to occur in this scorpion<sup>3,9</sup>.

### Spontaneous Resistance to Chloroquine in a Strain of Rodent Malaria (*Plasmodium berghei yoelii*)

DURING an investigation of sporozoite induced infections of *Plasmodium berghei yoelii* in mice, chloroquine was given in an attempt to eliminate the erythrocytic stages of the parasite. Unexpectedly, the parasite failed to respond to the drug.

Further tests have shown that this strain is spontaneously as resistant to chloroquine as are the highly resistant strains of *P. b. berghei* which have been artificially produced in the laboratory (ref. 2 and unpublished work of Warhurst).

The early history of the strain of *P. b. yoelii* (No. 17X) has been given by Landau and Killick-Kendrick<sup>1</sup>. This is the type strain of *P. b. yoelii* which was isolated by Landau and Chabaud<sup>2</sup> in the République Centrafricaine in April 1965 from *Thammomys rutilans*. The line we have investigated was derived from mouse 38L (infected blood, preserved at -70° C for 5 months) which had been infected from *Anopheles stephensi* batch 31 L (ref. 1). After two further cyclical transmissions, with three intermediate syringe passages, a sub-line was treated with chloroquine (15 mg/kg daily oral dose) on November 8, 1965, and found to be insensitive. After another 6 week period of low-temperature preservation and fourteen more cyclical transmissions, with twenty-one intermediate syringe passages in mice and rats, another sub-line of the strain was subjected to two more syringe passages in mice, and then tested for chloroquine resistance on December 12, 1966. After the strain had been through a further three passages in mice, another drug test was carried out on January 2, 1967; the last drug test described in this note was carried out after three more mouse to mouse passages on January 16, 1967. From May 1965 to December 1966 strain 17X had been through fifteen cyclical transmissions and twenty-eight syringe passages in the laboratory. Other than when sub-lines were being tested, the strain has never been exposed to antimalarial drugs in the laboratory. The action of chloroquine on this strain was compared with the action of the drug on an old laboratory strain of *P. b. berghei* (N), and on a recently isolated mosquito-transmissible strain of *P. b. berghei* (NK65) (ref. 4). Groups of five male Parkes-strain mice were used.

In the first experiment, we compared the action of chloroquine on *P. b. berghei* (strain N), and *P. b. yoelii* (strain 17X), by a method previously described<sup>5</sup>. On December 12, 1966, mice were inoculated intravenously with infected blood, and a single dose of the drug was given intraperitoneally 2 h later. Increases in latent periods of infection were then recorded. The dose-response curves are given in Fig. 1. The prolongation of the latent period of strain N is linearly related to the logarithm of the dose of chloroquine, but this is not so for strain 17X. In strain N, a dose of 40 mg/kg caused a delay of 4.2 days, but in strain 17X a dose of 40 mg/kg caused a delay of only 1.85 days. In the second experiment, a conventional 5 day drug test<sup>6</sup> was carried out as follows. The mice were inoculated intravenously on the first day with 10<sup>7</sup> parasitized erythrocytes, and drug doses were given intraperitoneally on the day of infection, and for 3 subsequent days. Blood films were taken on the day after the last dose of the drug, and the parasitaemias were evaluated. The results are expressed in

Fig. 2 as dose-response curves showing mean parasitaemias in the experimental groups (as a percentage of the parasitaemias in the control groups) plotted against logarithm of drug dose.

The difference in dose-response of the two strains is clear. In mice infected with strain *N*, 5 mg/kg given daily for 4 days completely prevented the appearance of parasites, while in mice infected with strain 17X a dose as high as 50 mg/kg merely reduced parasitaemia to 28 per cent of undosed controls. The dose-response line of strain 17X is relatively flat, and resembles the dose-response lines of artificially produced chloroquine-resistant strains of *P. b. berghei*<sup>2</sup>.

In the comparison of the action of chloroquine on strain 17X with that on strain NK65 of *P. b. berghei* made on January 16, 1967, a conventional 5 day drug test was carried out as in the second experiment described previously. In both experiments chloroquine was given in a dose of 5 mg/kg daily for 4 days. Strain 17X developed a parasitaemia which was 40 per cent of that of undosed controls, whereas strain NK65 developed a parasitaemia which was less than 3 per cent of the control. Chloroquine-resistance is therefore a special feature of strain 17X, and not merely a characteristic of freshly isolated strains.

The response of strain 17X to other antimalarial drugs is still in the course of investigation, but preliminary observations using the 5 day test indicate that it is sensitive (possibly hypersensitive) to pyrimethamine, sulphadiazine, and proguanil. It resisted a daily oral dose of 150 mg/kg of quinine hydrochloride but not of 300 mg/kg. It also resisted a daily intraperitoneal dose of 5 mg/kg of mepacrine hydrochloride but not 10 or 100 mg/kg. It was almost completely resistant to pamaquine given orally at sub-toxic doses (20 mg/kg) but not at doses (40 mg/kg) which killed most of the mice. These results suggest that there is a slight cross-resistance to mepacrine and quinine, but this is not as marked as that found in artificially prepared chloroquine-resistant strains of *P. berghei*<sup>2,6</sup>.

The results described here show that, although it has never before been exposed to antimalarial drugs, strain 17X is as resistant as are laboratory strains of *P. berghei* which have been produced by treatment of infected animals with chloroquine. The resistance appears stable, unlike artificially produced chloroquine-resistance<sup>2,6</sup>. These observations raise several interesting points. (1) Chloroquine-resistance may be a feature of all recently isolated strains of *P. berghei*. Most drug tests on *P. berghei* have been carried out on old syringe-passaged laboratory strains, which do not necessarily behave as do recently isolated ones. It is well known that freshly isolated strains of *Trypanosoma rhodesiense* are insensitive to doses of arsenical drugs which will eliminate old laboratory strains. On the other hand, our experience with strain NK65 showed that *P. b. berghei* is not similarly

Fig. 1. Prolongation of latent period (days delay) by single doses of chloroquine in strain *N* (○) and strain 17X (●) of *P. berghei*.

Fig. 2. Parasitaemias (as percentage of undosed control values) in mice infected with strain *N* (○) and strain 17X (●) of *P. berghei*, plotted against daily dose of chloroquine in the 5 day test.

resistant, even when freshly isolated and still infective to mosquitoes. (2) Chloroquine-resistance is perhaps restricted to the *yoelii* sub-species of *P. berghei*. We cannot be sure this is so, however, until other isolates of the sub-species have been investigated. (3) Because a spontaneously chloroquine-resistant strain of *P. berghei* has been found in nature, there seems to be no reason why the same should not apply to *P. falciparum*, which causes malignant tertian malaria of man. In South East Asia and South America, strains of *P. falciparum* have been found which are resistant to chloroquine<sup>7</sup>, while in Africa, where chloroquine has also been widely used as an antimalarial, there is no authenticated report of chloroquine-resistance. It seems likely that in *P. falciparum*, as in *P. berghei*, chloroquine-resistant strains may sometimes occur spontaneously.

We thank Mme. Irène Landau and Professor M. Yoeli for supplying strains of *P. berghei*; Dr. F. Hawking, Professor P. C. C. Garnham, Dr. J. Williamson and Dr. R. S. Bray for suggestions. Mr. R. Folwell gave technical assistance. This work was supported by a grant from the World Health Organization.

### Multiplication of *Drosophila* Hereditary Virus ( $\sigma$ Virus) in *Drosophila* Embryonic Cells cultivated in vitro

$\sigma$  VIRUS multiplies in *Drosophila* and confers to it a characteristic sensitivity to carbon dioxide<sup>1</sup>. Although many data have been collected about this virus, so far all virological and genetic investigations have been concerned with the complex system formed by the virus and the host organism. To understand better the relationships

between  $\sigma$  virus and its host at the cellular level, we have been developing techniques to cultivate *Drosophila* cells *in vitro* and infect them with  $\sigma$  virus.

We have shown<sup>2</sup> that it is possible to grow embryonic cells of *Drosophila melanogaster* in a relatively complex medium which imitates the composition of the *Drosophila* haemolymph, and is supplemented with 10 per cent foetal calf serum. These "primary" cultures have to be transferred after the sixth week. Successful sub-cultures were developed in microdrops under paraffin oil<sup>3</sup>. As long as the medium is changed frequently, the cells can be kept in good condition for many months and mitotic figures are observed often. They divide to form small continuous layers adhering to the bottom of plastic Petri dishes, on the areas corresponding to the drops. These "monolayer" sub-cultures reasonably could be expected to provide good material for investigation of the multiplication of  $\sigma$  virus.

The viral suspension we used came from *Drosophila* flies infected with a "thermo-resistant" viral mutant<sup>4</sup>. The insects were crushed with a definite quantity of our standard culture medium, and this crude extract, after centrifugation, was filtered through a 'Millipore' membrane (pore size 0.45 $\mu$ ). This sterile filtrate was used as the source of  $\sigma$  virus.

To infect the cells, the culture medium from a microdrop was removed and replaced by the viral suspension. After a 1 h adsorption period, this fluid was sucked up and fresh culture medium was substituted for it. The culture medium was changed regularly every 3 or 4 days. The infected microdrops were kept at 26°C. We systematically looked for infectious virus in the supernatant medium of the drops and determined the titre by the accurate biological method using *Drosophila* flies<sup>5,6</sup>: the viral content of every sample is assayed through the measurement of the mean incubation time of a set of about sixty inoculated *Drosophila*. The relation between the incubation time and the number of injected infectious units has been carefully established for the used viral strain, by the method of serial dilutions.

Two sub-cultures of *Drosophila* embryonic cells, transferred to microdrops under paraffin oil 2 months before, were infected with  $\sigma$  virus in the conditions which have been described. If the titre of the initial viral suspension and the volume of the drops are considered then the amount of virus which infected each of these cultures can be estimated as  $4 \times 10^3$  infectious units. From the second week after infection, the viral production became intensive and remained high and fairly constant until the end of the experiment. One of the cultures, when it was lost accidentally on the forty-fourth day after infection, had produced, if we add up the successive viral collections, about  $3 \times 10^5$  infectious units. The other culture was still in good condition on the sixty-ninth day. At this time, the cells of this culture were shaped from the bottom of the Petri dish and crushed in their last culture fluid. The total yield of this culture was found to be  $6 \times 10^5$  infectious units. No cytopathic effect was, however, observed; the cells appeared quite normal in the phase contrast microscope, and their multiplication was proceeding at the usual rate.

We can conclude that the  $\sigma$  virus multiplies in *Drosophila* embryonic cells cultivated *in vitro*. Starting with  $4 \times 10^3$  infectious units, the viral collection after 2 months amounted to approximately  $6 \times 10^5$  units. This viral production is equivalent to the maximal viral yield of one infected *Drosophila* fly. Although it is very difficult to estimate accurately the cellular content of a microdrop culture, it is undoubtedly smaller than the cellular mass of a whole fly. Furthermore, it must be noticed that the experiment was voluntarily stopped on the sixty-ninth day. Viral production had been proceeding regularly for many weeks, and the cells were still in excellent condition, so there is every reason to believe that the experiment could have been extended for a much longer time

and the total viral yield could have reached a value perhaps two or three times larger.

Thus, for the first time, it was possible to demonstrate a multiplication of  $\sigma$  virus in cultures of *Drosophila* cells. Further experiments of this type will result in a more accurate analysis of the relations between  $\sigma$  virus and the cells of its host, *Drosophila*.

### Techniques for recording the Activity of Aquatic Invertebrates

DURING recent investigations of burrowing in worms and bivalve molluscs<sup>1-3</sup> new techniques have been developed of continuously recording activity, because conventional methods which involved the attachments of threads or levers<sup>4,5</sup> proved of little use in investigating freely burrowing animals. The techniques described here allow observations to be made with the minimum of disturbance to normal activities. They involve the adaptation of equipment commercially available and are based on the measurement of either impedance or hydrostatic pressure changes.

Using an impedance pneumograph, a small oscillatory current (2  $\mu$ amp, 25 kc/s) may be passed between two fine wire electrodes attached one to each valve of a bivalve (Fig. 1,  $E_1$ ). Any movement of the valves affected the impedance between the electrodes and a voltage proportional to the change in impedance was fed to a pen recorder by either a.c. or d.c. coupling. With a.c. coupling (time constant 2.5 sec) opening or closing of the valves

Fig. 1. Diagram of *Mya arenaria* in natural position in sand (stippled) and under water showing position of electrodes.  $E_1$ , fine wire electrode, one of a pair attached to the valves to record opening and closing;  $E_2, E_3$ , wire electrodes fixed to 'Perspex' tube (P) to record movement of siphons.

Fig. 2. Recordings of activity of bivalves. *a*, *Margaritifera margaritifera* moving across the surface of fine sand. The pressure recording (above) shows a negative swing (*F*) at adduction (*A*) which is sustained during pedal retraction. Valve movements (gape) recorded by electrodes placed on the valves (*E*<sub>1</sub>, Fig. 1) with a.c. coupling to the recording equipment. Between adductions, after the valves have reopened, oscillatory pressure waves (*P*) indicate extension and probing of the foot. *b*, *Ensis arcuatus* digging into sand. The pressure wave shows a negative swing (*F*), which corresponds to those in *a*, followed by positive peaks (*W*) caused by ejection of water from the mantle cavity at adduction into the sand as depth of burial increases. Between each digging step (*F* or *W*) the foot makes three distinct probes (*P*). *c*, Siphon movement of *Mya arenaria* recorded by impedance pneumograph attached to electrodes (*E*<sub>2+3</sub>, Fig. 1) with d.c. coupling to pen recorder. Heavy line indicates closure of siphonal apertures. Retraction (*RET*) is followed immediately by partial protraction and a slow rather intermittent recovery to the initial length. Pressure recorded in cm of water.

appeared as positive or negative deflexions, respectively, about a preset level to which the pen returned when movement ceased; d.c. coupling was suitable for more static phenomena. Although limited by the length of wire attached to the electrodes, this method allowed continuous recordings to be made of bivalves burrowing and demonstrated that adduction of the valves occurred at each downward step of the shell into the substrate (Fig. 2*a*). The same method has also been used to record the movement of the siphons of *Mya arenaria* by mounting a pair of wire electrodes on either side of a 'Perspex' tube or arch placed over the siphon (Fig. 1). Siphonal movements now changed the impedance between the stationary electrodes (*E*<sub>2+3</sub>) (Fig. 2*c*). This technique allows continuous records to be made without the animal being in direct contact with the electrodes and has been successfully used for recording the movement of sea anemones and the burrowing of *Arenicola*.

Pressure recording is the basis of another method for investigating the movements of animals through sand, by the use of a Statham pressure transducer of maximum sensitivity 0.4 cm water pressure/cm pen deflexion. The transducer was connected to pressure tubing of 3 mm bore which led a few cm below the sand and had its rigidly fixed external opening protected from entry of sand grains by a coarse nylon mesh. The satisfactory operation of the equipment was checked by recording small ripples on the surface of the water above the sand. The recordings were calibrated in cm water pressure, but the absolute values had little meaning as they were affected by the distance of the animal from the tube and the dilatant properties of the sand/water mixture<sup>6</sup>. Using fine clean sand from an open shore, a negative pressure is recorded either by a probe applied manually or by the thrust of the foot of a bivalve during digging (Fig. 2*a*, *F*). The force applied disturbs the packing of the sand/water system and the available water no longer suffices to fill the enlarged spaces so that water tends to be drawn in. As would be expected, withdrawal of the foot from the sand also gives a negative effect, but the ejection of water from the mantle cavity of a bivalve beneath the sand causes a positive peak. This is shown in Fig. 2*b*, *W*, where it should be noted that the first adduction of the valves (*F*) gives a response similar to Fig. 2*a* but as depth of burial increases the pressure (*W*)

becomes more strongly positive. Because the size of the experimental tank also affects the external pressure recordings, these must always be related to direct observations of the animal's activity. When this has been accomplished, recordings of the digging of small molluscs or worms, free of any attached electrode, may be readily obtained and interpreted even when they are completely invisible beneath the sand.

Fig. 2*a* shows some of the details of locomotion made apparent by these techniques. The external pressure (above) has been recorded simultaneously with valve movement (below) during the locomotion of the freshwater clam, *Margaritifera margaritifera*, across an aquarium. At each step the valves were rapidly adducted (*A*) and more slowly reopened. Only the foot was beneath the surface of the sand and it repeatedly retracted (*F*), immediately after adduction, pulling the shell forward about 0.5 cm each time. Between retractions, extension and probing forward of the foot produced continuous oscillations of pressure (*P*) which also had some effect on the valves. A common feature of recordings of the locomotion of this and certain other bivalves, for example, *Cardium*, at the surface of sand was the opening of the shell before adduction. This possibly represents relaxation of the 'slow' adductor muscle fibres before rapid contraction of the 'fast' fibres.

## Studies on the Relations of Insect and Host Plant

### 1. Effects of Water Stress in Host Plants on Infestation by *Aphis fabae* Scop., *Myzus persicae* (Sulz.) and *Brevicoryne brassicae* (L.)

It is generally agreed that the reproduction of aphids is influenced by water stress in the host plant. The nature of this influence is, however, not so clear and both increases<sup>1</sup> and decreases<sup>2</sup> in the reproduction of aphids have been reported in connexion with such water stress. One effect of the shortage of water in plants is the hydrolysis of protein in the leaves<sup>3,4</sup>. Such enrichment of the phloem sap with soluble nitrogen would be favourable to aphids<sup>5</sup>. Another effect of water shortage in the plant is loss of cell turgor. This loss of turgor may be disadvantageous to aphids by reducing the assistance in food uptake provided by sap pressure<sup>6,7</sup>. Thus the effects on aphids of water shortage in the plant can be regarded in terms of two main interacting and largely conflicting factors: (1) the concentration of nitrogen, and (2) the pressure in the phloem (compare ref. 2).

Plants in the present greenhouse experiments were grown in vermiculite enriched with nutrients. To obtain reproducible degrees of water stress, the pots were watered to field capacity when weighing showed that a predetermined deficit (10, 50 or 90 per cent) of available water between field capacity and the permanent wilting point

had been reached. The plants were infected with a small number of aphids (ten in most experiments) and the population counted by washing the plants at the end of approximately 4 weeks. The experiments involved the following plant and aphid combinations: *Aphis fabae* Scop. on beans (*Vicia faba* L.), *A. fabae* and *Myzus persicae* (Sulz.) on marigolds (*Calendula officinalis* L.), and *M. persicae* and *Brevicoryne brassicae* (L.) on brussels sprouts (*Brassica oleracea gemmifera* Schulz). The mean number of aphids per plant at the end of each experiment is shown in Table 1.

Table 1. EFFECTS OF WATER STRESS IN HOST PLANTS ON THE REPRODUCTION OF *Aphis fabae*, *Myzus persicae* AND *Brevicoryne brassicae*

Host plant	No. of replicates	Aphid	Mean No. of aphids per plant on plants with water deficits (per cent) of:			Results
			10	50	90	
<i>Vicia faba</i>	11	<i>Aphis fabae</i>	1,304	1,160	1,263	No significant effect
	13	<i>Aphis fabae</i>	106	130	142	No significant effect
		<i>Myzus persicae</i>	273	340	171	90 per cent regime significantly lower than others ( $P < 0.001$ )
<i>Calendula officinalis</i>		<i>Aphis fabae</i>				
		<i>Myzus persicae</i>	196	488	210	50 per cent regime significantly higher than others ( $P < 0.001$ )
		<i>Brevicoryne brassicae</i>	211	186	155	Linear decrease in numbers with increasing water deficit significant ( $P < 0.05$ )

No effect of water stress could be observed with *A. fabae*, whereas the reproduction of *B. brassicae* decreased with increasing water stress. *M. persicae* showed a decreased reproduction at a water deficit of 90 per cent, and on brussels sprouts the increase in reproduction at a water deficit of 50 per cent was highly significant.

A possible interpretation of these results is that *M. persicae* gains more from an enrichment of the sap and is less dependent on phloem pressure than *B. brassicae*. The older leaves occupied by *M. persicae* are likely to show proteolysis and turgor reduction before the apex<sup>8</sup>, where *B. brassicae* normally feeds and in fact fed in this experiment. Nevertheless, the number of *B. brassicae* fell consistently with increasing water strain. In subsequent work with individual *B. brassicae* caged on the leaves, however, such a fall in reproduction with a shortage of water only occurred in old leaves, and at the apex reproduction actually increased<sup>9</sup>. With *A. fabae*, which is also mainly an apex feeder, Kennedy *et al.*<sup>2</sup> found that reproduction was significantly reduced only in their "very dry" regime, where the plants were considerably more wilted than in the 90 per cent deficit regime of the present experiments. This suggests that *A. fabae* is perhaps less dependent on phloem pressure than *B. brassicae*, but no evidence was obtained that the former aphid benefited from sap enrichment with increasing water shortage to an extent where enrichment more than compensated for a reduction in turgor pressure.

Some indirect evidence consistent with a lower dependence on pressure of *M. persicae* than of the two apex feeding aphids has been obtained by one of us (H. F. v. E.) with the artificial feeding of aphids on sucrose solutions without pressure through 'Parafilm' membranes<sup>10</sup>. Six replicate batches of ten apterous adults of each species were kept on each of twenty-five diets. These diets represented all combinations of five concentrations of sucrose (0–30 per cent) and five concentrations of sinigrin (0–2 per cent). The survival of the aphids was assessed daily, and the time at which 50 per cent of the insects had died was determined by plotting the probit of the percentage mortality against the logarithm of the time (days). As analysis showed that sinigrin had no significant effect, the survival of aphids on increasing concentrations of sucrose could be compared directly.

Fig. 1. The mortality of *Aphis fabae* (●—●), *Myzus persicae* (○—○) and *Brevicoryne brassicae* (▲—▲) on various sucrose concentrations fed through 'Parafilm' membranes.

The results (Fig. 1) show that *M. persicae* feeding on a pressure-less diet obtains greater benefit from an increase in the concentration of sucrose than *A. fabae* or *B. brassicae*. This is in agreement with the inference drawn here that *M. persicae* may be less dependent on a food supply under pressure than the other two aphid species studied.

## II. Effects of Water Stress in Host Plants on the Fecundity of *Myzus persicae* (Sulz.) and *Brevicoryne brassicae* (L.)

IN a further investigation of the problem of the effects of water stress in host plants in pots on the reproduction of aphids, individuals of *Myzus persicae* and *Brevicoryne brassicae* have been studied on young, mature and old leaves of brussels sprouts (var. 'Jade Cross') which were growing in three water regimes<sup>1</sup>. All experiments were conducted at 20° C in a daylength of 16 h. Fourth instar nymphs in leaf cages (twelve replicates) moulted to adult and larviposited, and one of the offspring was reared to adult in each cage. Throughout the reproductive life of these adults, their progeny were removed daily and counted to measure fecundity (Fig. 1).

On young and mature leaves the fecundity of both species of aphid increased with water shortage. These increases may be related to enrichment of the phloem sap with soluble nitrogen compounds recirculated from the senescing leaves.

On old leaves the two species of aphid responded differently. The fecundity of *B. brassicae* diminished with increasing water shortage. This fall may be associated with reduced phloem turgor pressure and/or increased sap viscosity effectively reducing the quantity of sap ingested by the aphid<sup>2</sup>. Reduced fecundity was manifest at relatively little water shortage as compared with previous reports<sup>2</sup>. This suggests that *B. brassicae* is considerably dependent on turgor pressure for feeding, which is consistent with earlier work. The fall of reproduction with the shortage of water, previously reported for *B. brassicae*, occurred, however, when the aphids were feeding on the apex of the plant<sup>1</sup>. This inconsistency with the present experiments may well have resulted from too many of the aphids leaving the plants in the dryer regimes, either as alates or restless apterae. Experiments (to be published) support this belief.

On old leaves the fecundity of *M. persicae* was greater on plants in the medium regime, suggesting that the aphids were able to benefit from the enrichment of sap at this level of water shortage. The detrimental effect of loss of turgor was only evident in the dry regime where fecundity was lower. This is also consistent with earlier work.

It is clear that the response of aphids to a shortage of water in the host plant varies with the species of aphid and age of the leaf on which they are allowed to feed, as well as with the species of the host plant<sup>3</sup>. The results of the present experiments are consistent with the view that *M. persicae* is less dependent on turgor pressure for feeding than *B. brassicae*, although both aphids appear to benefit considerably from sap enrichment during host plant water shortage. These deductions are in accord

with the normal site of feeding of these two species of aphid on crucifers. *B. brassicae* most frequently feeds at the "turgid, nitrogen-rich" apex of the plant, while *M. persicae* occupies the "nitrogen-rich" senescing leaves which, during the summer months, may experience considerable and frequent fluctuations in turgidity (compare ref. 4).

In accordance with Kennedy, Lamb and Booth<sup>2</sup>, this interpretation assists in a reconciliation of the conflicting reports of the effects of host plant water shortage on aphids<sup>2,5,6</sup>. It is important to note, however, that lower phloem turgor pressure may be more important in reducing the duration and/or frequency of feeding by the aphids (increasing restlessness) than in directly reducing the rate of ingestion of sap, though the latter may be a causal mechanism of the former; in addition, other host plant factors, such as cell carbohydrates, minerals and pH, may have made an important contribution to the results.

## PSYCHOLOGY

### Role of the Neocortex in Acquisition of Avoidance Conditioning

AFTER a series of experiments which demonstrated that an impairment of maze learning resulting from the ablation of cortical tissue was proportional to the extent of the lesion and not dependent on its location, Lashley<sup>1</sup> postulated that all areas of the neocortex have a general or non-specific function in learning. This he called the mass action effect. Recently, mass action has received convincing support from investigations with cortical spreading depression (refs. 2-4 and unpublished work of R. B. Ross and I. S. Russell, and I. S. Russell, D. Kleinman and H. C. Plotkin), where it has been repeatedly demonstrated that functional hemidecorticated rats require two to four times as many trials as normal animals to learn an escape or avoidance response. The present investigation is an attempt to extend the knowledge of the mass action effect, which, until now, has remained a descriptive phenomenon rather than an explanation of the role of the cortex in behaviour. The hypothesis is that one of the important functions of the neocortex is that it is concerned with the encoding of the information input to the central nervous system. The intertrial interval was used as a means of manipulating this information input.

Estes<sup>5</sup> has suggested that the intertrial interval determines the extent of change of the stimulus situation from trial to trial because of the random fluctuation of stimulus elements. If the animal is conceived as drawing a stimulus sample from the environment at each trial, then a short intertrial interval will result in response to the same or a similar sample on successive trials. If, however, a long intertrial interval is allowed, as a consequence of which a more substantial turnover of stimulus elements will take place, then the samples of successive trials are likely to be more varied. This would result in a broader sample of the available stimulus complex being responded to over a smaller number of trials. The response acquired will then be more rapidly adopted, because a less stereotyped response to irrelevant or non-critical stimuli will occur. An implication of the above hypothesis of cortical function

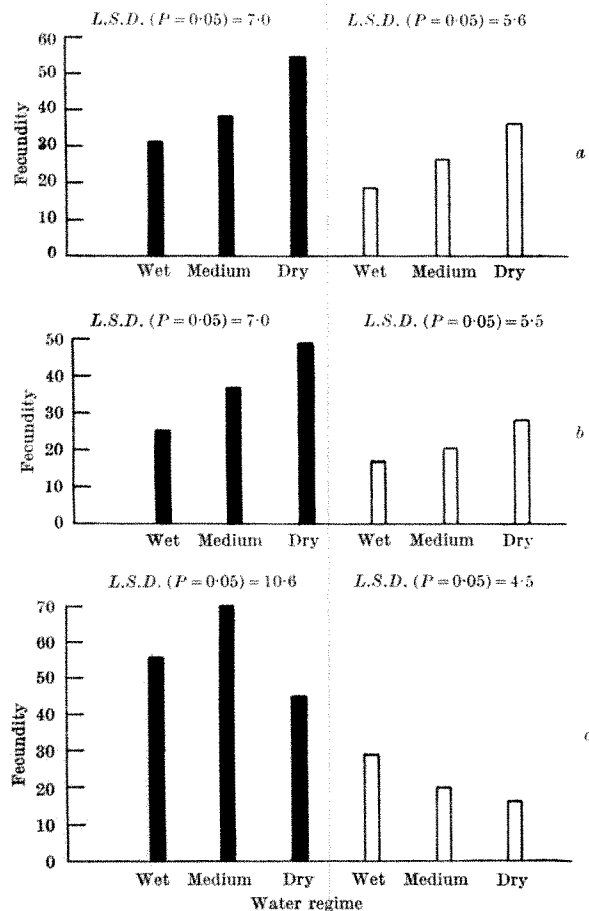

Fig. 1. Mean fecundity of apterous virginoparae of *Myzus persicae* (black columns) and *Brevicoryne brassicae* (white columns) on three leaf ages of brussels sprouts in three water regimes at 20° C. a, Young leaves; b, mature leaves; c, old leaves.

is that the sampling and fluctuation of stimulus elements are determined in part by the neocortex. Thus it seems that an interaction will obtain between the intertrial interval and the amount of functional cortex available to the animal.

A straight runway was employed for the avoidance conditioning. A delay of 5 sec followed the onset of the conditioned stimulus (buzzer) in the start box, before a current of 0.6 m.amp (unconditioned stimulus) was delivered to the grid floor of the starting box and alley. If an animal reached the safe goal box before the onset of the unconditioned stimulus, an avoidance response was recorded. Ninety-six male hooded rats were run over twenty trials each day for two consecutive days. These were divided into three groups of equal size, which comprised normal controls, unilaterals (spreading depression in one hemisphere), and bilaterals (spreading depression in both hemispheres). Each group was further sub-divided into four sub-groups, corresponding to the intertrial intervals of 15, 30, 60 and 240 sec. Spreading depression was produced by applying filter-paper pledgets soaked in 25 per cent potassium chloride solution to the dural surface which overlies the parieto-occipital cortex. Trials were only begun after all signs of placing reflexes had been abolished.

Table 1. AVERAGE VALUES OBTAINED ON DAY 1 AND DAY 2 FOR TOTAL NUMBER OF AVOIDANCES (AV) AND RESPONSE LATENCIES (LT)\*

	Day 1			Day 2	
	ITI	AV	LT	AV	LT
Normal controls	15"	9.4	61	12.7	40
	30"	15.1	42	18.0	21
	60"	14.4	40	17.6	25
	240"	15.0	37	17.5	23
Unilaterals	15"	0.9	111	5.9	73
	30"	6.5	74	12.7	44
	60"	6.7	72	11.6	45
	240"	6.5	88	13.2	41
Bilaterals	15"	0.0	157	1.3	144
	30"	0.0	258	0.5	165
	60"	0.0	215	0.9	157
	240"	0.1	255	1.9	143

\* Given in units of 0.001 min.

The results of the experiment are given in Table 1. Inspection of the avoidance totals and latencies for the normal controls reveals that the 15 sec sub-group was inferior to the other sub-groups, the latter yielding asymptotic performance from the 30 sec intertrial interval. Further, all sub-groups demonstrated improvement from day 1 to day 2. A three factor analysis of variance with repeated measures on one factor was performed on the data, and both intertrial interval and day factors were found to be highly significant.

The unilateral animals showed a similarly significant intertrial interval effect, which emerged as identical in form to that obtained by the controls; and furthermore, a very considerable improvement in performance was shown from day 1 to day 2. Table 1 shows, however, that all the unilateral sub-groups displayed a significant learning impairment during both days when compared with the controls. Counter to the prediction which had been made, no interaction was obtained between cortical and intertrial interval factors.

The bilateral animals showed no learning in forty trials in terms of avoidance responses, and so comparisons with the other groups as well as within group comparisons must be made by way of response latencies. These functionally decorticate animals, while significantly inferior in their performance to the other two groups, showed a reversed day 1 intertrial interval trend. The 15 sec sub-group showed performance superior to the other three sub-groups, the latter again asymptoting at the 30 sec intertrial interval, but at an inferior performance level. Clearly, this is the opposite to what was found for the controls and unilaterals; there is a significant interaction between cortex and intertrial interval factors when the latencies of all three groups are compared. Furthermore, while the other bilateral sub-groups yielded a considerable

saving on day 2, the 15 sec sub-group showed none at all, and the performance levels of all four sub-groups on the second day were similar.

A qualitatively parallel intertrial interval effect has been shown to hold for both the controls and unilaterals, and so core differences between the two groups cannot be directly extracted on these grounds. Nevertheless, the mass action effect was manifested in terms of a considerably greater number of superstitious responses being adopted by the unilaterals (approximately six times as many for unilaterals as for normals), as well as in the unilaterals which display persistent spontaneous regressions, the latter probably being a reflexion of a protracted early stage in the learning.

The lack of interaction between cortex and intertrial interval factors demonstrates that varying the interval in the goal box has the same effect on the performance of an animal, whether one or both cerebral hemispheres is functional. The bilateral sub-groups did not show the usual intertrial interval effect, and this suggests that the effect is mediated by the neocortex in the normal intact animal. Thus, while an interpretation of the mass action effect in terms of the function of the cortex as the primary mechanism involved in stimulus sampling and encoding has not been shown to be incorrect, this investigation has given it only indirect support.

In view of the fact that bilateral animals gave no avoidance responses in forty trials, although a decrease in latencies did occur, it would be prudent to discuss their performance, not as learning, but as an adaptation to the situation. The 15 sec sub-group (the results of which have been replicated in a second group) displayed minimal freezing and regressive responses, unlike the other bilateral animals. The degree of stereotyping was marked and is reflected in the relatively low variance of this sub-group. These apparently contradictory characteristics—the rapid (as reflected in the low latency) although limited adaptation was offset by unadaptive stereotyped responses—could tentatively be explained by the following two discrete, though related, mechanisms. The first relates the observed effects of the intertrial interval directly to the acquisition-storage aspects of the problem; the second to factors extraneous to, though intimately linked with, the neural substrate of behavioural change. (a) The bilateral animal, lacking the normal cortical encoding, and possibly holding, mechanism is partially compensated by a very short intertrial interval acting directly on a limited sub-cortical store; and (b) Brutkowski<sup>6</sup> has described, as a consequence of prefrontal ablation in dogs and monkeys, behaviour which appears to arise from the inability of the animals to inhibit tendencies resulting from training or preference and thereby continuing one response to the exclusion of others. He further reports that this condition was exacerbated in a conditioning experiment in which a 15 sec intertrial interval was employed. Spreading depression in the neocortex of the lissencephalic rat involves areas homologous with the prefrontal cortex of higher mammalian species, and so Brutkowski's findings suggest that the performance of the bilateral animal could be considered in these terms. This would only apply to the bilateral preparation, since a similar deficit in the unilateral animal would be nullified by the functional contralateral hemisphere.

I thank Dr. I. S. Russell for his help.

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the I.E.R.E. Medical and Biological Group, at Savoy Place, London, W.C.2), at 2.30 p.m.—Discussion Meeting on "Automatic Processing in Nucleonic Isotope Studies".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. G. Sheals, Dr. P. H. A. Sneath and Mr. L. Watson: "Numerical Taxonomy".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. P. J. Hilton: "The Homotopy Type of Compact Polyhedra".

UNIVERSITY OF LONDON (at the School of Oriental and African Studies, London, W.C.1), at 5 p.m.—Prof. Jean-Luc Chambard (Paris): "Atlas of an Indian Village. III, The Village Territory: Agrarian Problems".\*

UNIVERSITY OF LONDON (at the Institute of Neurology, National Hospital, Queen Square, London, W.C.1), at 5.30 p.m.—Prof. Ernst Gutmann (Prague): "The Motor Unit in Old Age".\*

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 6 p.m. Discussion Group meeting on "Dose-Time Factors in Radiotherapy". 8 p.m.—Ordinary meeting. Dr. H. F. Cook: "Training in Radiological Physics".

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. W. B. Curtis, Mr. L. Tasker and Mr. J. R. Taylor: "The Theoretical and Practical Considerations of the Use of Water Soluble Resins in the Electrodeposition of Paint".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Twickenham College of Technology, Edgerton Road, Twickenham), at 6.30 p.m.—Mr. P. R. Styles: "Medical Electronics".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Madame Nicole Leger (Paris): "Aspects of the Pharmacology of Anthelmintic Drugs".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at the Royal Army Medical College, Millbank, London, S.W.1), at 7.30 p.m.—Laboratory Meeting. Chairman: Prof. G. Macdonald.

## Friday, March 17

BRITISH INSTITUTE OF RADIOLOGY (at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2), at 10 a.m.—British Radiological Protection Association Symposium on "The Radio-Iodines in Man".

NUTRITION SOCIETY (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 10.30 a.m.—Symposium on "Food Habits and Nutritional Status of Minority Groups in the United Kingdom".

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W.1), at 1 p.m.—Dr. E. Vander Donckt: "pK of Excited States".

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting of the I.E.E. History of Technology Group and the Newcomen Society, at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. R. L. Smith-Rose, C.B.E.: "Early Days in Radio Research".

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the AUTOMATIC CONTROL GROUP OF THE I.MECH.E., at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion Meeting on "The Present State of Stability Theory" opened by Dr. A. G. Dewey, Prof. G. D. S. MacLellan, Mr. F. C. Parks and Prof. C. Storey.

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. M. Nicholson: "The Resolution of Conflict" (First Caradog Jones Lecture).

UNIVERSITY COLLEGE LONDON (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. E. Gutmann (Prague): "Neurotrophic Relation between Nerve and Muscle Cells".\*

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. G. E. Bacon: "Looking at Solids with Neutrons".

## Saturday, March 18

ASSOCIATION FOR SCIENCE EDUCATION (at Parliament Hill School, London, N.W.3), at 2.30 p.m.—Symposium on "The Teaching of Science for the C.S.E.".

## Monday, March 20

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Royal Society and the I.E.R.E. Computer Group, at Savoy Place, London, W.C.2), at 2.30 p.m.—Colloquium on "Automated Cartography: Scientific Needs and Engineering Possibilities".

INSTITUTE OF ACTUARIES (in Staple Inn Hall, High Holborn, London, W.C.1), at 5 p.m.—Prof. P. G. Moore: "Operational Research in Business".

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5 p.m.—Dr. P. S. Hewlett: "Synergism and Potentiation in Insecticides".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"Rendez-vous du Diable" (colour film).

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Mr. F. Bennett: "Monomer Approach to Flame Retardancy".

## Monday, March 20—Tuesday, March 21

GRIMSBY COLLEGE OF TECHNOLOGY (at Nuns Corner, Grimsby)—Symposium on "Modern Developments in Food Preservation".

## Monday, March 20—Wednesday, March 22

BIOCHEMICAL SOCIETY (at Trinity College, Dublin)—489th Meeting. Included in the programme will be an Ordinary Meeting and a Discussion Forum on "Metabolic Role of Vitamin A".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER or ASSISTANT LECTURER (preferably with interest in ecological and population genetics) in ZOOLOGY—The Registrar, University of Manchester, Manchester 13, quoting Ref. 17/07/Na (March 17).

ASSISTANT LECTURER (preferably with research interests and experience in botany and archaeology and with an appreciation of modern physical techniques) in QUATERNARY PALAEOECOLOGY—The Secretary, The Queen's University, Belfast, Northern Ireland (March 18).

SENIOR RESEARCH ASSISTANT (with an honours degree in metallurgy together with postgraduate research or industrial experience) in the DEPARTMENT of METALLURGY for an investigation of the structure and properties of cast and wrought austenitic steels—The Personnel Officer, Brunel University, Kingston Lane, Uxbridge, Middlesex (March 18).

ASSISTANT LECTURER in GENETICS—The Registrar, University College of Swansea, Singleton Park, Swansea (March 20).

LECTURER in ENGINEERING MATHEMATICS—The Secretary, The Queen's University, Belfast, Northern Ireland (March 20).

TUTORS (2) in the DEPARTMENT of GEOGRAPHY to assist with tutorial groups involving small groups of students and to provide assistance in practical map classes—The Registrar, University College of Swansea, Singleton Park, Swansea (March 23).

BIOLOGIST (with an interest in crop physiology) in the SYSTEMS SYNTHESIS SECTION of the DEPARTMENT of BIOLOGY, to work on the theoretical aspects of plant and crop growth—The Secretary, The Grassland Research Institute, Hurley, Maidenhead, Berkshire (March 24).

LECTURER (physicist or engineer with active interests in the field of thermodynamics and fluid mechanics) in MECHANICAL ENGINEERING—The Secretary of the University Court, The University, Glasgow (March 27).

ASSISTANT LECTURER or LECTURER in the DEPARTMENT of APPLIED MATHEMATICS and MATHEMATICAL PHYSICS—The Registrar, University College of South Wales and Monmouthshire, Cardiff (March 28).

LECTURERS or ASSISTANTS (2) (with a good honours degree and preferably some postgraduate experience) in CELL BIOLOGY—The Secretary of the University Court, The University, Glasgow (March 29).

LECTURER in DEPARTMENT of ZOOLOGY, University of Tasmania—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, March 31).

LECTURER (with specialized experience in general pharmacology especially in the field of physical pharmacy) in PHARMACEUTICS—The Registrar, The University, Nottingham (March 31).

TURNER AND NEWALL RESEARCH FELLOWS in ENGINEERING, INORGANIC CHEMISTRY, PHYSICS and allied subjects—The Registrar, The University, Manchester, 13 (March 31).

PROFESSOR of MICROBIOLOGY—The Registrar (Room 30, O.R.B.), The University, Reading (April 3).

LECTURER (with experience of teacher training and special interests in the philosophy of education and related theoretical bases) in the PHILOSOPHY AND THEORY OF EDUCATION in the School of Education, University of Zambia—The Inter-University Council, 33 Bedford Place, London, W.C.1 (April 10).

POSTDOCTORAL RESEARCH ASSISTANTS in the DEPARTMENT of CHEMISTRY for studies on organic compounds of beryllium and aluminium in collaboration with Prof. G. E. Coates and Dr. K. Wade—The Registrar, University of Durham, Old Shire Hall, Durham (April 10).

ASSISTANT LECTURER (interested in experimental psychology) in PSYCHOLOGY—The Registrar, The University, Liverpool, 3, quoting Ref. RP/412 (April 11).

LECTURER (with a special interest in the fields of structural geology and petrology) in GEOLOGY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, April 15).

SECOND CHAIR OF PURE MATHEMATICS—The Registrar, The University, Sheffield (April 15).

LECTURER in the DEPARTMENT of ORGANIC CHEMISTRY, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, April 30).

LECTURER in the DEPARTMENT of ORGANIC CHEMISTRY, University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, May 20).

LECTURER or ASSISTANT LECTURER (with a medical or scientific qualification) in VIROLOGY in the DEPARTMENT of BACTERIOLOGY and VIROLOGY—The Registrar, The University, Manchester, 13, quoting Ref. 25/67.

LECTURER or SENIOR LECTURER in PLANT PHYSIOLOGY in the DEPARTMENT of ARTS, SCIENCE and EDUCATION—The Registrar, University of London Goldsmiths' College, London, S.E.14.

READER (with high qualifications and research experience in a branch of science related to vision) in OPHTHALMIC or PHYSIOLOGICAL OPTICS—The Academic Registrar, The City University, St. John Street, London, E.C.1.

SENIOR LECTURER and LECTURERS (2) (with a good degree in mathematics or statistics with special interests in statistics or electro-magnetic theory or a branch of pure mathematics) in the DEPARTMENT of MATHEMATICS—The Clerk to the Governing Body, Northern Polytechnic, London, N.7.

**\*RHODANILE BLUE**

An entirely new type of basic dye conceived and synthesized for the first time by Dr. Edward Gurr with the object of providing a new research tool. This unique polychrome dye possesses interesting and unusual properties. It has been found to have a number of very useful applications both in polarized and ordinary light microscopy; for example, it provides a distinctive stain for fibrin.

### APPOINTMENTS VACANT

#### EXPERIMENTAL OFFICER QUEEN MARY COLLEGE (UNIVERSITY OF LONDON)

An Experimental Officer is required for work in connection with the UNIVERSITY OF LONDON INTERCOLLEGIATE RESEARCH SERVICE for Chemistry and Related Sciences. He will be responsible for the running and maintenance of a Decca electron paramagnetic resonance spectrometer under the general supervision of Dr. K. D. Sales. Previous experience in this field is not essential, but applicants should either be graduates in Electrical/Electronic Engineering or possess equivalent qualifications or experience. Opportunities will also be available to develop the spectrometer and to take part in the research programme. Initial salary according to age and experience on scale rising to £1,680 per annum.

Applications, with relevant details, to be sent to the Registrar, Queen Mary College, Mile End Road, E.1, naming two referees. (1045)

#### UNIVERSITY OF OTTAWA DEPARTMENT OF GEOLOGY OTTAWA CANADA

Applications are invited for two staff positions in the fields of PLEISTOCENE GEOLOGY and processes and Stratigraphic Palaeontology. Applicants should be prepared to initiate and carry out research programmes and to conduct courses in these fields. Rank and salary depend upon qualifications and experience.

Requests for further information, and applications should be sent to the Chairman, Department of Geology, University of Ottawa. Closing date May 10. (1054)

#### UNIVERSITY COLLEGE OF NORTH WALES BANGOR

##### DEPARTMENT OF AGRICULTURE

Applications are invited for the post of RESEARCH ASSISTANT in this Department for work in connection with the effects of shelter on physical environment, animal performance and behaviour. Applicants should be Honours graduates in agriculture, agricultural science, or geography. The Research Assistant will be expected to register for a higher degree. Salary in the range £600 to £800.

Further particulars are obtainable from, and applications should be made by March 31, 1967, to the Professor of Agriculture, University College of North Wales, Memorial Buildings, Bangor. (1187)

#### HERIOT-WATT UNIVERSITY EDINBURGH

DEPARTMENT OF BREWING AND  
BIOCHEMISTRY  
Professor D. J. Manners, M.A., Ph.D.,  
D.Sc., F.R.I.C., F.R.S.E.

#### LECTURER IN BREWING SCIENCE

Applications are invited from Honours Graduates, with research or industrial experience, for the post of Lecturer in the above Department.

Salary scale for Lecturers is £1,470 to £2,630 with placing according to qualifications and experience. Superannuation under F.S.S.U.

Further details and form of application, which should be returned not later than April 1, may be obtained from the undersigned.

DUNCAN I. CAMERON,  
Secretary of the University.  
(1105)

## CSIRO

### AUSTRALIA

#### DIVISION OF FOOD PRESERVATION

### PLANT BIOCHEMIST OR PHYSIOLOGIST

Applications are invited for appointment as Plant Physiologist or Biochemist with the Organization's Division of Food Preservation. The headquarters of the Division are situated at Ryde, Sydney, New South Wales, but the appointee will be located at the Plant Physiology Unit, which is housed in the School of Biological Sciences at the University of Sydney, Sydney, New South Wales.

The research programme of the Division of Food Preservation includes many aspects of the physical and biological sciences related to the needs of the food industry. The Division has a staff of over 90 scientists working in the fields of physics, chemistry, biochemistry, plant physiology, microbiology and food science.

The Plant Physiology Unit, operated jointly by the Division and the University, conducts research on the role of extra-nuclear DNA in cellular differentiation, regulation of chloroplast formation by the phytochrome system, mechanisms of respiratory control, nitrogen metabolism of senescing leaves, and biochemistry of ripening in banana fruit. A wide range of scientific equipment is available. Members of the Unit may have opportunities for supervision of graduate students.

The appointee will join a research group working on the genetic and metabolic control of differentiation and ageing processes in plant cells.

Applicants should have a Ph.D. degree in a relevant field, or have had postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability. Applications from persons with research experience in nucleic acid metabolism are especially invited.

**SALARY:** Depending upon qualifications and experience within the ranges of: \$A5,071–\$A6,409 p.a. or \$A6,673–\$A7,729 p.a.

An applicant having outstanding qualifications and experience may be appointed within the range of: \$A7,991–\$A9,209 p.a.

Salary rates for women are \$A428 p.a. less than the corresponding rates for men. Promotion within CSIRO to a higher classification is determined by merit.

The duration of the appointment will be determined in consultation with the successful candidate; some applicants may prefer a fixed term appointment for three years, in which case consideration will be given to the continuation of F.S.S.U. arrangements. Fares paid for the appointee and his dependent family. If the appointee is at present permanently domiciled outside Australia, return fares will be paid at the conclusion of a fixed term appointment. Further particulars supplied on application to:

Mr. R. F. Turnbull, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House Kingsway London, W.C.2,

to whom applications (quoting Appointment No.: 301/30) should be addressed by the 14th April, 1967. (1172)

#### SOUTH AFRICAN COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH

## BIOCHEMIST

REQUIRED BY THE NATIONAL NUTRITION RESEARCH  
INSTITUTE IN PRETORIA

Duties will involve studies of the biochemical and metabolic effects of various toxins (mainly mycotoxins) on the tissues of experimental animals and of man. Training and experience in cellular biochemistry (e.g., cell fractionation studies, enzyme studies on tissues) will be a recommendation.

**Minimum qualifications:** D.Sc. or Ph.D. in Biochemistry.

**Salary:** Commensurate with qualifications and experience in the following range: R4,650–R6,000 p.a. (£2,325–£3,000).

**Benefits:** Generous leave privileges, Pension Scheme, Group Insurance, Vacation Bonus on Public Service basis, Medical Scheme and five day week.

Applications should be sent to: The South African Science Office, Chichester House, 278 High Holborn, London, W.C.1, Not later than 28th March, 1967. (1174)

## AMATEURS AND PROFESSIONALS

THE report of the Sutherland Committee on liaison between the British universities and government establishments is a mouse of a document—a good mouse as far as it goes, but without a proper sense of its own importance. What the committee has done is to compile a catalogue of ways in which universities and establishments can derive more benefit from their mutual existence without radically affecting the principles on which their relationship is based. The committee has been marvellously thorough in spelling out the ways in which one university or another establishment is willing to consider the transfer of people, so that the report will be a godsend to young graduates looking for a cosy berth where they can earn a living and work for a Ph.D. at the same time, as well as to vice-chancellors turned recruiting sergeants. But this is unfortunately only a part of the story, valuable but small. What the circumstances require is a much more radical examination of the ways in which the relationship between the universities and the establishments might be transformed not for their separate or even joint benefit, but so as to make fuller use of the resources they both employ.

That said, it is obviously sensible that the universities and the establishments should work more closely together whenever this is possible. This is where the committee is on sure ground. Its enquiries have apparently revealed that the establishments are eager for closer collaboration, which is something to be grateful for. It is particularly welcome that the committee has joined the growing clamour that the movement of people between the civil service and the universities should not be needlessly impeded by administrative difficulties about pensions and removal expenses. It will also be valuable if the committee can win support for the notion that new research establishments should wherever possible be sited near universities. The research councils, particularly the MRC and the ARC, are already aware of this need, but other public corporations and government departments are woefully ignorant of the way in which a functional laboratory and a university can stimulate each other. And, of course, there are great opportunities for more joint appointments between research establishments and universities, more part-time lecturers, and more collaborative research projects.

The Sutherland Committee is on much less certain ground in its advocacy of more widespread delegation of responsibility for postgraduate teaching from universities to the establishments. The committee would like to see more postgraduate students farmed out to the establishments, and more of those who work in the establishments entitled to submit a description of the research they do as raw material for a Ph.D. It is understandable that the establishments

should be keen on these arrangements—at the very least they help with recruitment. But the committee is surely far too casual in its conclusion that the anxieties of the universities are not “justifiable”. It is hardly fair to say that the universities fear they will be “denuded” of postgraduate students. To the extent that the loss of people is in any sense important, what the universities worry about is the possibility that they will lose the brightest of their students. But the real cause for worrying is concerned much more directly with the character of postgraduate teaching. British universities are already awakening to the need that the traditional Ph.D. dissertation on original research should be supported by more deliberate teaching in related fields. It is only natural that they should ask awkward questions about the capacity of government establishments to provide a sufficiently rounded further education for postgraduates. The Sutherland Committee is right in believing that the establishments and the universities could profitably work more closely together, but a more sensitive discussion of the obvious real problems would have made its report much more convincing.

These, however, are niggling points. A much more obvious defect of the committee's work is that it has ignored the most serious set of problems in the interaction between the universities and the establishments—the balance of resources between the two kinds of institutions. It is, of course, entirely proper that there should be some overlap between them. It is understandable, for example, that the establishments should seek to round out programmes of directed research by undertaking more long-term projects. The result is that some of the research at the establishments is essentially academic. Indeed, the establishments are often better equipped than the universities for academic work, perhaps because their programmes as a whole derive a sense of urgency from some military or industrial connexion. For the establishments, of course, these circumstances are entirely welcome, and there is no doubt that they add to what is called morale. But are they also in the interests of the universities? And of the country as a whole? On the face of things, at least, resources might be better employed if more of the work of the establishments were farmed out to the universities, on a contract basis or by simple grant, with no strings attached. There are difficulties on both sides, but they are not insuperable. The trouble is that it is impossible to know just where the balance should be struck without careful study. It is a pity that the Sutherland Committee did not tackle this useful job. As things are, the evidence the committee has compiled of the willingness of the establishments to help with teaching can be interpreted not only as a proof of goodwill but also as a

sign that the establishments have been endowed with resources which might have been better spent in universities.

## WHIMPER, NO BANG

THE dispute between the British universities and the Government about the proposal that students from overseas should pay higher fees has ended in an anti-climax. The statement by the vice-chancellors (see page 1059) bristles with discontent, but Mr. Crosland will have his way, and fees will be increased in the autumn by a factor of roughly three. The fact that the Government has agreed to set up a hardship fund for students who will be badly hit by the new regulations will repair some of the damage, although it would obviously have been better for the reputation of the Government if this proposal had not been wrung from it by a storm of protest. There remain two separate kinds of issues to be resolved.

The level of fees which the universities should charge is in itself an important issue. The protest about the raising of fees for students from overseas has been levelled at the discriminatory character of this proposal, and there is good reason to fear some of its repercussions. But there is a good case for a general increase in the tuition fees for all students at British universities. The Robbins Commission was only voicing a view that is widely held when it recommended a general increase, largely on the grounds that the universities would then be less directly dependent on a single source of funds—the University Grants Committee. A more realistic scale of charges would also help to remind the universities of the real costs of their operations, and might therefore be a spur to a greater concern for efficiency. If the Government is now prepared to have serious discussions on these problems, the vice-chancellors will have something to be pleased about. They would, however, be mistaken if they thought that they could establish a higher scale of fees without making a spontaneous and convincing demonstration that they are prepared to operate in a thoroughly modern way. In the long run, they will also have to reconcile themselves to a much greater variation from one university to another.

The dispute about overseas fees has also questioned in an acutely disturbing way the character of the relationship between the universities, the University Grants Committee and the Government. Theoretically, the universities are autonomous, and are protected by the UGC from direct interference by the Government. On this occasion, it now seems plain, the UGC was not consulted about the specific proposal that fees for overseas students should be increased, while the universities as a whole have had to act as the Government decreed. To be sure, some universities agreed with the Government's proposal, and others had no stomach for a fight, but even so, this sequence of events

lends support to those who think that the UGC is no longer an effective buffer. Changing circumstances, and particularly the growing scale of public support for the universities, have made it inevitable that there should be important changes in the past two decades. Unfortunately the universities have been slow to recognize what has been going on. The result is that they have no collective means of resisting pressure from outside—or of applying it when necessary. In the discussions which lie ahead, the Committee of Vice-Chancellors must work not merely for more realistic fees but for recognition as the proper negotiating body on all matters of this kind.

## STARTING FROM SCRATCH

THE Natural Environment Research Council has produced its first report (see page 1059), and this is something to be grateful for even if it is later than it should have been. Now it should at least be possible to make more reasonably informed guesses about the way in which the new council will tackle the exceedingly difficult job of supporting research in a field which is necessarily ill-defined, and which is almost certain to remain like that. To judge from what the first report has to say, planning has been conditioned by the character of the laboratories which have fallen into the council's hands—the Institute of Oceanography, the various institutes concerned with the geological sciences and now tidily grouped together, and a number of marine biology laboratories, for example. The Nature Conservancy is also an inner force to be reckoned with, especially in its occasional role as the professional counterpart of the Council for the Preservation of Rural England. Nobody will be surprised that oceanography and marine biology get the fullest treatment in the report.

If, however, the immediate future is filled with sensible projects, the more distant future is probably as much of a puzzle for the research council as for those who may work with it. The council seems to have pinned its faith in a utilitarian concept of its influence. In places the first report reads like a précis of some of the things said in the name of the International Biological Programme. There is talk of making the Atlantic more productive of fish, and of the way in which a better understanding of wave motion may in the long run help both with the design of ships and the disposal of coastal effluents. But can the council hope to hold to this line without also undertaking the technology of exploitation? Will it be found drilling in the North Sea one day? And what will be its relations with the universities? These are some of the questions which the committee of the National Academy of Sciences on oceanography has been trying to answer (see *Nature*, 213, 937; 1967). It is to be hoped that by a year from now, the Natural Environment Research Council will have answers of its own.

## NEWS AND VIEWS

### More for British Science

THE Civil Estimates for 1967-68, issued earlier this week (see page 1066), suggest that the total expenditure from public sources on research and development will increase by roughly 4 per cent in the financial year ahead. Although details are as yet available for only 90 per cent of the British Government's expenditure in this field, the total is likely to increase from £433 million in 1966-67 to between £450 and £460 million in 1967-68. These figures do not, of course, include the expenditure of private industry and the foundations on the support of research and development. Although the rate of growth in the public sector has evidently slackened off, the increase in the coming year will outstrip the GNP, which is not expected to increase at all.

Table 1. RESEARCH COUNCIL SPENDING (£ MILLION)

	1966-67	1967-68
SRC	33.9	36.6
NERC	6.2	7.7
MRC	11.9	14.2
ARC	10.3	11.9
	<u>62.3</u>	<u>70.4</u>

Now that the full details of the estimates for the year ahead are available, it is clear that the rate of growth of support for basic research will be even greater, and more like 14 per cent over the year than the increase of 9 per cent suggested by the figures in the Vote on Account published a few weeks ago. The budgets of the four research councils concerned with the natural sciences will increase from £62.3 million in 1966-67 to £70.4 million in the financial year immediately ahead, as shown in the Table. The expenditure of the Social Sciences Research Council will grow even more rapidly, as befits a new organization. The Department of Education and Science will also be spending more in its direct grants to scientific causes. Thus expenditure on the Office of Scientific Information will grow from £290,000 to £370,000.

### Beating a Retreat

THE Committee of Vice-Chancellors and Principals has now agreed to recommend to universities that they should charge the increased fees for students from overseas suggested by the Department of Education and Science at the end of last year. In a statement earlier this week, the committee said that it had been mollified by an undertaking from the Secretary of State for Education and Science that there should be consultation on the long-term problem of university fees, and that the hardship fund intended to help overseas students with special problems would in reality be generous. The fund, whose existence was announced at the height of the clamour against discriminatory fees some weeks ago, is intended to help students already embarked on courses (*Nature*, 213, 853; 1967).

Although the vice-chancellors have for all practical

purposes conceded what the government has been asking for, they make a great show of their displeasure. The making of a public statement is in itself a sign of this. They also repeat their complaint that a discriminatory fee structure is bound to have unfortunate repercussions within the university system and without. They complain that they were not consulted before the original statement on fees for students from overseas, and that the University Grants Committee "appears to have been bypassed". The Committee of Vice-Chancellors even puts on record its disagreement with the official view that the University Grants Committee was consulted by saying that it understands the UGC was "consulted some six months ago and not consulted on the specific decision which the government announced on December 21".

In the immediate future, the Committee of Vice-Chancellors is likely to press for a general increase of university fees from something like £70 a year at present to nearly twice that amount at the end of the decade.

### Research into Environment

THE first report of the Natural Environment Research Council (H.M.S.O., 8s.) covers the first 10 months of the existence of the council, up to March 31, 1966. This was a period of some administrative chaos, which explains why there is little solid information in the report and why it has taken so long to appear. The council took over the Nature Conservancy, the National Institute of Oceanography, the Institute of Geological Sciences and the Hydrological Research Unit, and assumed responsibility for fisheries research, marine and freshwater biology, seismology and geomagnetism, long-term forestry research, and the awarding of grants and postgraduate training awards to universities. These activities are now run by five main committees, soon to be joined by a sixth when the council takes over responsibility for the British Antarctic Survey on April 1. Sir Graham Sutton is the chairman of the council, and the chairmen of the main committees are Lord Howick (Nature Conservancy), Professor J. C. Mitcheson (Geology and Geophysics), Professor M. J. Lighthill (Oceanography and Fisheries), Mr. N. A. F. Rowntree (Hydrology) and Professor M. V. Laurie (Forestry and Woodlands).

The budget of the council for the period of the report was almost £3.8 million. Just over £1 million went to the Institute of Geological Sciences, £853,000 to the Nature Conservancy, £440,000 in grants to universities, and £288,000 for training awards and fellowships. Since the period of the report, the Geological Survey has been amalgamated with the Overseas Geological Survey, and a start has been made in creating a centre of geochemical research in London. The plans for this centre are complete, although it has yet to be given a name. It will be in the Gray's Inn Road premises previously occupied by the overseas division of the Geological Survey, and will bring together the two mass spectroscopy sections at present in Oxford and the survey's premises in Young Street, London. When complete, the centre will have a staff of 80-90 people.

The British Antarctic Survey, previously the responsibility of the Commonwealth Office, moves to the council at the beginning of April. Whether there will be any change in the management of the survey has

not yet been decided. The only hint of a change in the work of the survey is the intention of expanding the biological side, on advice from the Council for Scientific Policy. The budget of the survey, however, is unlikely to be increased, unless the magic word "oceanography" is muttered sufficiently often. The council has two oceanographic enthusiasms; one is to study the North Atlantic, for some people are afraid that it is getting significantly colder, which could have catastrophic effects on the stock of fish; the other is to investigate ways of extracting uranium, gold, and silver from sea water by ion exchange. The process is not commercial yet, but might be if uranium prices increased, or if the French view on the price of gold prevailed. The Nature Conservancy, bloody but unbowed after its unavailing struggle with Imperial Chemical Industries, Ltd., over the building of a reservoir in Teesdale, has not yet decided whether to take ICI up on its offer of £100,000 for a crash course of research into the botany of Teesdale. It should make up its mind quickly, before ICI forgets it ever made the offer.

## Technology Gap

LAST week (March 6) a one-day meeting at the Institution of Electrical Engineers under the title "Making the Bosworth Report Work" discussed the means of attracting more able graduates into industry. It has been a constant theme of the Ministry of Technology, which sponsored the conference, that industry and the universities should draw closer together, but it is not yet clear whether its pious pleas are having any effect.

In some respects university departments are showing themselves more responsive than industrial firms—apart, of course, from those traditionally employing graduates. At the beginning of the year, four of the physics staff at University College, London, opened a consultative practice (as a limited company, New Industrial Concepts, Ltd.) to advise firms with process control and inspection problems. Their experience with manufacturers has shown that small British companies in particular seldom know how even well-established electronic techniques can help them; really advanced methods are a closed book. "There are still an astonishing number of standard jobs done by hand and measurements made by eye . . ."

The group—Dr. R. Stebbings, Dr. D. G. Davis, Dr. A. Boksenberg and Dr. A. C. H. Smith—have already nearly completed their first commission—to solve a control problem (including fabricating a unit) in the manufacture of specialized electric light bulbs—and have a satisfied client. They have undertaken that their commercial excursion shall not interfere with their lecturing and research commitments at University College, but apart from this the college has made no conditions and has been encouraging. So has the Ministry of Technology, which has put the group in touch with its regional liaison officers. The group have not asked for a grant so they have not got one.

Rather different is the scheme headed by Dr. Kenneth Ball at the Department of Mechanical Engineering at the University of Liverpool, now in its fourth year and supported by a grant of £32,000 from the Science Research Council. In this case the academic team has sought opportunities to get into the shop

and design specific pieces of plant for actual use. "Industrial jobs provide us with a laboratory where we can create a design, and then look backwards at it," says Dr. Ball. "Not until a real job is tackled can one identify either the central problems of systems design or of teaching systems designing . . ." The most substantial job tackled so far has been in association with Ruston and Hornsby, Ltd. (matching a freshly designed turbo-charger to its diesel engine), and evolving computer software to project further engine development.

## Best Buy in Space

AN agreement signed on March 8 between the European Space Research Organization (ESRO) and the U.S. National Aeronautics and Space Administration may mean that British taxpayers will have to contribute more towards ESRO launchings than towards other means of putting their experiments into satellites. The new agreement lays down that ESRO will in future pay for satellite experiments launched by the United States. In practice, however, well-established research groups in Britain have hitherto been able to include their experimental equipment in American satellites without payment of any kind except that which is invested in hardware. Groups from University College, London, the Culham Laboratory of the Atomic Energy Authority, and the R.A.F. Institute of Aviation Medicine are among those who have been able to find space in American satellites.

From an exclusively British point of view, ESRO launchings are expensive, and now increasingly so, because the British contribution towards the running costs of the organization, including the cost of launching rockets, is roughly 25 per cent of the total budget. This contribution is payable whether or not British experiments are included in ESRO satellites although the costs of salaries and equipment for particular experiments come out of separate national budgets. The first ESRO launch under the agreement with the United States will be the satellite due to be launched into a highly elliptical orbit in late 1968 to record events in the magnetosphere at around the next solar maximum. The contract with NASA is for just under \$4 million and the cost of the satellite and its equipment will be roughly the same again. Later American launchings of ESRO satellites will be relatively cheaper because of the comparative sophistication of their payloads costing roughly £8 million for the two.

In the circumstances, the British national space programme, much maligned, may yet be the second best buy, at least on the surface. The *Black Arrow* satellite payloads now in the offing should be comparatively cheap to launch if only because a large part of the cost will be hidden in the defence budget.

## Another Exhortation

THE United States National Committee for the International Biological Programme has now published a more detailed outline of the kind of research it is anxious to encourage when the second phase of the operation begins in July this year. The document *U.S. Participation in the International Biological Programme* is the second of two reports to have been produced by the committee, and is to be had from the

National Academy of Sciences. Dr. Roger Revelle, chairman of the committee, lists in his general introduction the "three related objectives—human welfare, scientific advance and international scientific co-operation". He says that biologists can "contribute uniquely to human welfare only by advancing scientific understanding, and the basic premise of the International Biological Programme is that the growth of understanding will be accelerated by international co-operation among the world's biologists". Dr. Revelle explains that in the United States the U.S. National Committee will work closely with the Interagency Coordinating Committee responsible for the efforts of federal agencies in this field.

So far, the work planned for the International Biological Programme, which will last for five years or thereabouts, consists chiefly of conferences. The Committee on Environmental Physiology has plans for six conferences on specific topics during 1967. The Committee on the Productivity of Marine Communities is planning five conferences on a regional basis. Others of the seven sections of the IBP have plans for various regional conferences and of others organized around specific subjects. From the outline programme, it is clear that the organizing committees are at this stage keeping a prudently open mind about the kind of work which can most usefully co-ordinate the work of individual laboratories in the years ahead. At the same time, the organizers are anxious that working scientists should formulate proposals for research in the areas of science considered to be most in line with the objectives of the IBP. Although the IBP is not itself a grant-giving agency, it does intend to scrutinize research proposals to see whether they accord with the aims of the IBP. Evidently the U.S. National Committee is hoping, however, that its certificate will carry weight. Time will no doubt tell.

## Out of the Record

*The Zoological Record* seems to have allowed its centenary to slip by with uncommon lack of ceremony. The *Record* was established in 1864 to keep zoologists informed of the most recent researches in their subject and has led a very chequered career. It started as the private undertaking of the publisher Mr. Van Voorst, under the editorship of Dr. Albert Günther, passed to the Zoological Society of London, thence to the Royal Society and finally back again to the Zoological Society, which now both compiles and publishes it. Early in its career when private enterprise failed, a Zoological Record Association had to be established to keep the publication solvent, and for several years the British Association provided an annual grant of £100 in its support. Expenses are now met in part by donations from institutions and individuals in the British Commonwealth and the United States, from the International Union of Biological Sciences and the Naples Zoological Station.

The *Record* is an annual compilation from more than 4,000 journals and is divided into twenty sections. Eighteen of these deal with a class or family of animals, and the other two with "Comprehensive Zoology" and a "List of New Genera". The information is presented in the form of three indexes. There is a bibliographical index arranged alphabetically under authors, with titles of research papers given in French, German or

English. The subject index is arranged under broad headings, and in the latest volume for "Pisces" the economics section includes, for example:

"Fisheries research.—Aspects of marine fisheries research, Lucas; tropical fisheries research, McConnell; freshwater fisheries research, Pentelow."

"Effects on fishes of industrial effluents.—Effect of heated effluents, Alabaster; effects of sewage effluents, Lloyd; Young; . . ."

A systematic index provides information relevant to a particular species or to groups of the phylum concerned together with details of new taxa.

## Molluscan Structure

THE growing number of scientists engaged on research on the Mollusca, and the suitability of these animals as experimental material, was plain at the international symposium held last week under the auspices of the Zoological and Malacological Societies. There were contributions on such varied topics as the molluscan fauna of the rain forests of the Solomon Islands, the fine structure of muscle and the bivalved gastropods. The gaps in knowledge of excretion in this phylum were dealt with by another speaker, and workers from the Free University of Amsterdam and the University of Southampton emphasized the neurosecretory activities of gastropods. Professor G. A. Kerkut and his associates from Southampton described aspects of the fine structure of the brain of *Helix* and the pharmacology of certain of its neurones, while speakers from Professor J. Lever's Department in Amsterdam gave accounts of studies of the nervous system of *Lymnaea*. Investigations of neurosecretion in the Mollusca are, as yet, in their preliminary stages, but they represent an important new field in which neurosecretion may be more closely related to the activity of the whole animal.

A new theory to account for the mechanism of calcification of the molluscan shell was put forward in a stimulating paper by P. S. B. Digby. Observations on the mussel *Mytilus edulis* have indicated that at the growing margin of the valves, the outer surface of the periostracum is acid and the inner is alkaline. Measurements of potential across this superficial membrane, which consists of quinone tanned proteins, showed that the outer side becomes increasingly negative and the inner positive as the mantle edge exerts suction on the permeable periostracum and outer layer of the valve around the shell margin. The membranous periostracum acts as a semi-conductor and electronic charge is considered to flow through the material. Calcification is attributed to electrode action at the inner side of this membrane producing alkalinity which precipitates lime. The process of calcification of the molluscan shell was thus thought to be comparable with that of the crustacean cuticle and of mammalian bone, in that they all represent electrochemical processes.

In a contribution on the burrowing activities of bivalves, E. R. Trueman pointed out how the shell of these animals operates as the basis of a hydraulic system by means of which the strength of the adductor muscles is used in digging by the production of high hydrostatic pressures. He suggested that the bivalved form of the shell may be an adaptation for active burrowing into or over soft substrates.

## Immunochemical NMR

by a Correspondent in Molecular Biology

NUCLEAR magnetic resonance spectroscopy has not so far been much used in the study of proteins or indeed of nucleic acids. Its great potential in this field is only now being recognized more widely, and with improvements in instrumentation and the appearance during the past year or so of a number of strikingly successful applications, an increasing number of problems will be found to lend themselves particularly well to this approach.

The unique advantage of NMR for the study of polymers lies in its sensitivity to freedom of motion. Sharp signals are obtained only when the motion of the nuclei under observation (most commonly protons) is very rapid: this situation will obtain for small molecules in solution or for flexible polymers with rapid segmental motion—a denatured protein, for example. When the polymer becomes rigid, as in a globular protein or an  $\alpha$ -helical polypeptide, the signal broadens, sometimes to a degree at which it effectively disappears. The possibility exists, moreover, of identifying sharp signals with a particular class of protons, as, for example, those of particular amino-acid side chains in proteins. The possibilities for the study of conformational changes, with perhaps isolated observation of particular groups, will commend themselves for many purposes.

The NMR technique also offers a method for the observation of ligand-binding to macromolecules, because signals from the ligand nuclei will be broadened when the molecule is immobilized by binding to the macromolecule. A good example of the potential of the method in the protein field is given by Haugland *et al.* in the current issue of *Biochemistry* (6, 498; 1967). They have studied the interaction of an antibody with a hapten but with a more refined procedure which permits the use of minimal concentrations. Rather than proton resonance, they observe that of the chlorine ( $^{35}\text{Cl}$ ) nucleus, which is present in the hapten. The hapten is a mercurial, 2,4-dinitro-4'-(chloromercuri)diphenylamine. The experiments are carried out in sodium chloride solution, and the existence of free chloride ions, which can exchange with the mercury-bound chlorine in the hapten, leads (as shown in an earlier article by Stengle and Baldeschwieler) to an amplified line-broadening effect. Because the hapten is added to the antibody, so a broadening of the  $^{35}\text{Cl}$  resonance is observed, and it is possible to perform a titration by this means to give the stoichiometry of the association at antibody concentrations down to  $6 \times 10^{-7}$  M. When dinitrophenyllysine is added to the complex, the line-width again decreases, showing that the mercurial hapten is displaced.

The observed broadening of the signal when the mercurial hapten is bound defines a limiting rate of exchange of chlorine between hapten and solvent, and demonstrates that the hapten is fully exposed. The line-width will also reflect the rotational freedom of the chlorine in the hapten—that is to say, in effect the flexibility of the binding region. It is interesting to note that unbound hapten does not interfere with the measurements, and that weak interactions can therefore be studied; the authors state that a 1 per cent level of binding can be detected.

## Nuclear Hyperfine Spectroscopy

PROFESSOR J. F. DUNCAN writes: The majority of papers delivered at the International Conference on Nuclear Hyperfine Spectroscopy held at Victoria University of Wellington, New Zealand, from October 17–21, 1966, were concerned with Mössbauer spectroscopy, but there were also contributions on nuclear magnetic resonance and electron spin resonance. The conference was attended by visiting scientists from Australia, Brazil, the Congo, Germany, India, Israel, Japan, New Zealand, United Kingdom, U.S.A. and U.S.S.R., and consisted of four principal review papers and about forty short research papers.

The first of the review papers was given by Professor H. Frauenfelder, who described the use of Mössbauer spectroscopy in physics. New techniques, such as populating the excited state by coulombic excitation, or using scattering techniques which enable higher energy states to be more readily detected, were described. The second review paper by D. P. Craig outlined problems in calculating the interaction energies within a crystalline matrix. E. Fluck reviewed the current state of nuclear magnetic resonance spectroscopy of heavy nuclei, such as phosphorus-31, fluorine-19 and cobalt-59. The last review paper by V. J. Goldanskii was a most informative contribution on recent advances of Mössbauer spectroscopy in chemistry. It outlined the rapidly increasing applications in the field of structural determination, and discussed work carried out in Russia on investigating some biologically important compounds, including several components of RNA.

The research papers covered a wide range of topics—theoretical work, magnetic fields, chemical structure problems, solid state problems, instrumentation, general effects—and concluded with a most stimulating paper by P. Hillman on Mössbauer studies on hearing.

The range of topics discussed in the research papers may be judged from the following brief summary. N. N. Greenwood assessed NMR techniques for measuring the stability of complexes; there are two methods for determining formation constants: the first can be applied where there is rapid exchange between free and complexed ligand, the second when there is also dissociation as well as exchange. Hyperfine interaction constants from NMR spectra of low spin ferric compounds was discussed by Golding and by Kurland. M. A. Collins discussed the measurement of nuclear hyperfine coupling constants in complex spectra. The calculation of  $g$  and hyperfine tensors for small molecules in double quantum transitions in ESR spectra was described by J. E. Wertz, and B. G. Wybourne discussed the use of pseudo-interactions in calculating spectroscopic properties and the effect of ionic contributions to  $S$  state rare-earth ions. A. J. F. Boyle spoke on relaxation and the Mössbauer effect in small magnetic particles, and gave a theoretical description of the effect of electron spin relaxation on the energy spectrum when there is an axis of quantization which remains fixed despite the time averaging introduced by the relaxation. J. J. Spijkerman and F. C. Ruegg have developed instrumentation for routine and high precision Mössbauer spectroscopy. R. E. Bailey and J. F. Duncan have shown that the three compounds  $\text{FeP}$ ,  $\text{Fe}_2\text{P}$  and  $\text{Fe}_3\text{P}$  fall into a regular array, and that the magnetic field at the iron atom is determined by

the number of nearest neighbour phosphorus atoms.

The week's discussion showed that many of the problems in this field require a detailed knowledge, not only of the physics of the system, but also of the chemistry of the molecules under investigation. The need to cross fertilize between the two disciplines was reflected in the composition of the conference, which was attended by roughly equal numbers of physicists and chemists.

## Select Committee

THE Select Committee of the House of Commons on Science and Technology continued to hear evidence from Sir William Penney, Chairman of the U.K. Atomic Energy Authority, when it resumed discussion of the British reactor programme on March 9. The costs of the OECD high temperature reactor (*Dragon*) were carried largely by the United Kingdom and Euratom, Sir William said. Each paid about 45 per cent, and another £4.5 million would be needed to carry the project on until 1970; the total cost would then be £31 million. Britain was prepared to go on, but because of political difficulties Euratom was unable to make up its mind. If Euratom refused, he said, the project might well come to an end; it would certainly be expensive to continue without Euratom, and the possibility had not yet been given serious thought.

Sir William said that Britain was not developing a small reactor, although the authority was keeping an eye on developments elsewhere. There seemed no point, he said, since nuclear propelled ships had so far shown no chance of being more economical than conventional ones, and there was no other obvious use for small reactors. For fast reactors, the authority had calculated capital costs of £50 per kW installed, and running costs of 0.3d. per kWh. So far as he was aware, no other source of power could compete with this—natural gas might be able to, but he had seen no figures. Mr. Eric Lubbock said that in the United States figures of \$100 per kW installed were already being quoted, but Sir William replied that comparisons were hard to make, and that running costs were just as important as capital costs.

Diversification was an essential part of the authority's programme, Sir William said. Despite this, and the fact that the total staff of the authority had been allowed to decline from 40,000 in 1962 to 32,000 in 1966, there were still too many people on the payroll. Reduction of staff would be largely by wastage, and 20 per cent of the staff would move to non-nuclear work in the next five years. The chief item in the diversification programme was desalination, but the best market for this, Sir William said, might turn out to be with a conventional power source rather than with nuclear power. Under the Ministry of Technology umbrella there was an enormous amount of materials research—at Harwell, Farnborough, and the National Physical Laboratory. If this could be integrated—although not geographically concentrated—considerable improvements ought to be possible. Asked how easy it is for people to leave the authority, Sir William said that pension rules were liberally interpreted, but it was hopeless expecting men from Harwell to go into schoolteaching—there simply was not enough money in it.

## Parliament in Britain

IN a written answer in the House of Commons on March 6, Mr. Roberts stated that Science Research Council awards are provided for research training or an approved course of postgraduate instruction but not primarily for obtaining a higher degree. In 1962–63 there were 1,623 qualified applications and 1,610 awards were made: for 1963–64 the corresponding figures were 1,968 and 1,932; for 1964–65, 2,567 and 2,507; for 1965–66, 2,928 and 2,785; and for 1966–67, 3,096 and 2,775. Mr. Roberts declined to consider lowering the standard of qualification for awards and added that in 1966 the number of research and advanced studentships awarded by the Science Research Council was about 18 per cent of the number of students graduating in that year and provided support for about half the total number of graduate students in science and technology. In 1962–63 the Science Research Council awarded 48 fellowships tenable in the United Kingdom; 28 NATO and Council fellowships tenable abroad; and 16 fellowships to British scientists in North America to enable them to return to the United Kingdom. For 1963–64, the corresponding figures are 44, 18 and 20; for 1964–65, 52, 27 and 32; for 1965–66, 83, 25, 41; and for 1966–67, 54, 26 and 41. A proposal by the Science Research Council to increase the value of fellowship awards is being considered in relation to relevant aspects of incomes policy.

REPLYING for the Government in a debate in the House of Lords on Overseas Information Services on March 8, the Minister of State for Foreign Affairs, Lord Chalfont, admitted the need for careful examination and planning of such services and also that the development of modern communication systems had made such effort more important. He saw no reason for any further co-ordinating process than that which normally took place through the Cabinet and its committees: each Minister was responsible for co-ordinating the information activities of his department. Lord Chalfont maintained that reductions so far made and planned in United Kingdom based staff were fully in accordance with the recommendations of the Plowden Committee. He also mentioned that special campaigns had been instituted on such subjects as Britain's achievements in desalination and in the development of nuclear energy. Sir Thomas Rapp's report reviewing the work of the B.B.C. External Services had been received in August 1965 with important recommendations for capital expenditure to improve the audibility of B.B.C. programmes, and the government had now asked Sir Harold Beeley to review the overseas information services with a view to reconciling their effectiveness with the containment of public expenditure.

IN a written answer in the House of Commons on March 7, the Joint Parliamentary Secretary, Ministry of Technology, Dr. J. Bray, stated that booklets describing methods of determining eight toxic substances in factory atmospheres, based on research carried out in the Laboratory of the Government Chemist for the Ministry of Labour, were published by H.M.S.O. in 1966. Booklets on chromic acid mist, phosgene, nitrous fumes and mercury were in the press and methods for hydrogen fluoride, ozone and organic di-isocyanates are being investigated.

## University News:

## London

PROFESSOR A. O. MACK, professor of dental prosthetics in the University of Newcastle upon Tyne, has been appointed professor of dental prosthetics at the Institute of Dental Surgery from September 1, 1967. Professor P. D. Wall, professor of physiology at the Massachusetts Institute of Technology, has been appointed professor of anatomy at University College from August 1, 1967.

## Loughborough

PROFESSOR E. J. RICHARDS, dean of the Engineering Faculty, professor of applied acoustics, and director of the Institution of Sound and Vibration Research in the University of Southampton, has been appointed vice-chancellor, in succession to Dr. H. L. Haslegrave. At Vickers Armstrong, Ltd., from 1945-50, he was aerodynamic designer of the Viscount and Valiant.

## Nottingham

PROFESSOR R. E. COUPLAND, professor of anatomy at Queen's College, Dundee, has been appointed to the Foundation chair of human morphology in the new Medical School, and Dr. J. R. A. Mitchell, first assistant to the Regius professor of medicine in the University of

Oxford, has been appointed to the chair of medicine in the Medical School.

## Appointments

DR. J. A. HALL, at present assistant general manager for international activities of the United States Atomic Energy Commission in Washington, has been appointed deputy director general in charge of the Department of Administration of the International Atomic Energy Agency. Mr. A. A. Wells, the current deputy director general, is returning to Washington to become chairman of the USAEC Atomic Safety and Licensing Board Panel.

PROFESSOR R. R. WILSON, professor of physics and director of the Laboratory of Nuclear Studies at Cornell University, has been appointed director of a proposed National Accelerator Laboratory.

## Announcements

THE Corday-Morgan medal and prize have been awarded by the Chemical Society to Professor J. I. G. Cadogan, Purdie professor of chemistry in the University of St. Andrews, and Professor R. Mason, professor of inorganic chemistry in the University of Sheffield. Professor Cadogan received his award in recognition of his contribu-

The North Atlantic Treaty Organization sponsors each year a number of international meetings and courses at which scientific topics are discussed at an advanced level. The scientific programme of each meeting is decided by the director, who also arranges for selection of the participants, and publicity. Interested scientists should therefore write to the appropriate director for further details and to check the place and time of the meetings.

tions to the organic chemistry of trivalent phosphorus compounds and Professor Mason received his award for his contributions to the structural chemistry of inorganic and biologically important compounds.

THE Institution of Structural Engineers, in collaboration with the Aluminium Federation, is offering a research scholarship of two years duration, worth £700 per annum, plus fees of about £80 per annum. The winner will carry out research in the use of light alloys in structural engineering, and should be British and under the age of 30 on October 1, 1967.

CHANGES are announced by the Royal Aeronautical Society in the rules of the Kremer Competition. The main prize of £5,000, endowed by Mr. Henry Kremer, for a man-powered flight around a figure-of-eight course with two turning points not less than half a mile apart has been increased to £10,000. The competition will now be open to all nations, instead of being limited to the British Commonwealth. In addition there will be another competition, open initially to members of the Commonwealth, over an easier course half a mile long in the form of a slalom. The prizes for this easier test will be £2,500, £1,500 and £1,000 for the first three competitors to complete the course; if the prizes are not won entirely before December 31, 1968, the rules may be revised. Rules for the £10,000 competition may be revised if the money is not won before December 31, 1973.

A CONFERENCE on the "Rheology of Building and Road Materials", organized by the British Society of Rheology, is to be held in Sheffield during April 4-5. Further information can be obtained from Dr. G. H. Tattersall, Department of Building Science, University of Sheffield (Materials Laboratory), Shearwood Road, Sheffield 10.

AN international symposium on "Discrimination Learning", organized by the Experimental Analysis of Behaviour Group, is to be held at the University of Sussex on April 5-6. Further information can be obtained from Dr. R. M. Gilbert, Department of Psychology, University of Aberdeen, Old Aberdeen.

A ONE day symposium on "Lubrication of Textile Machinery" will be held at the Manchester Institute of Science and Technology on April 13. Further information can be obtained from the Conference Department, The Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

A SHORT course on "Recent Advances in Chromatography" will be held in the Lanchester College of Technology, Coventry, during April 13-14. Further information can be obtained from Dr. C. W. Went, Lanchester College of Technology, Priory Street, Coventry.

A SYMPOSIUM on "Aspects of Nitrogen Metabolism and Utilization in Plants", sponsored by the Agricultural Committee of the University of Bristol, will be held at Long Ashton Research Station during April 18-19. Further information can be obtained from the Scientific Liaison Officer, Long Ashton Research Station, Long Ashton, Bristol.

THE 1967 spring informal symposium of the Gas Chromatography Discussion Group of the Institute of Petroleum will be held at the Royal Institution, 21 Albemarle Street, London, W.1, on April 28. Further information can be obtained from Miss J. Healey, Institute of Petroleum, 31 New Cavendish Street, London, W.1.

A DISCUSSION on "Helicoidal Macromolecules in Solution" is to be held by the Société de Chimie Physique during their sixteenth annual meeting in Paris during May 2-6. Further information can be obtained from Professor G. Emschwiller, Société de Chimie Physique, 10 rue Vauquelin, Paris 5<sup>e</sup>.

A SHORT course entitled "Copolymers—Their Preparation and Properties" will be held at the Lanchester College of Technology, Coventry, during May 3-4. Further information can be obtained from Dr. A. F. Johnson, Department of Chemistry and Metallurgy, Lanchester College of Technology, Coventry.

THE fourth annual national colloquium on "Information Retrieval" will be held in Philadelphia during May 3-4. Further information can be obtained from Mrs. Regina M. Hildreth, Fourth Annual National Colloquium on Information Retrieval, Radio Corporation of America, Electronic Data Processing, Camden, New Jersey, U.S.A.

A CONFERENCE on three growth prospects of the chemical industry: agricultural chemicals, pharmaceuticals and plastics, is to be held by the Chemical Group of Aslib at Attingham Park, near Shrewsbury, during May 15-17. Further information can be obtained from Mr. J. R. Clew, 42 Bedford Road, Horsham, Sussex.

AN international conference on "Essential Oils Production in Developing Countries", organized by the Tropical Products Institute of the Ministry of Overseas Development, will be held in London during May 15-19. Further information can be obtained from the Director, Tropical Products Institute, 56-62 Gray's Inn Road, London, W.C.1.

ERRATUM. In the article "Canine 'Field' in Sexual Dimorphism of Tooth Size" by S. M. Garn *et al.* (*Nature*, 212, 1501; 1966), two subscripts were inadvertently transposed in the sentence at the bottom of page 1501 which should read: "The same tendency holds in the mandible, though less completely, with  $I_2$  exceeding  $I_1$  in percentage sexual dimorphism and  $P_1$  exceeding  $P_2$  in the same respect".

CORRIGENDUM. In the article entitled "Resistance to Water Transport in Plants" by O. V. S. Heath (*Nature*, 213, 741; 1967) line 16 of the second column should read "ratio was 19:1".

## CORRESPONDENCE

### Information Exchange Groups

SIR,—This is to correct a complete misinterpretation in the statement by the secretary of the Commission of Editors of Biochemical Journals of the "primary original purpose" of the IEGs as unqualifiedly stated in "Biological Journals and Exchange Groups" (*Nature*, 213, 547; 1967). The actual purpose was to provide, on a test basis, a means for quick communication within the total pool of research manpower at work in some sharply focused research area. What they communicated was theirs to decide, as much as what scientists communicate in their private professional correspondence—which can, indeed, be regarded as the prototype of the IEG. Behind this purpose was the belief that quick communication of research findings, from an originating laboratory to all other laboratories in which there was significant probability of need for the information, accelerated scientific discovery in the research area. The reader will appreciate how untenable the notion is as presented in the article—namely, that the original purpose of the IEGs was limited to "rapid exchange of informal suggestions, comments, queries and general discussion".

Yours, etc.,

ERRETT C. ALBRITTON

National Institutes of Health,  
Bethesda,  
Maryland, U.S.A.

# Estimates for Science

The Civil Estimates, published this week, give notice of what the British Government intends to spend in the coming financial year on non-military operations. The estimates for the Ministry of Technology are complicated by the recent takeover of the Ministry of Aviation, but show some significant changes in emphasis. Those for the Department of Education and Science show a steady advance in educational and scientific spending, despite the credit squeeze.

THE Civil Estimates for the Ministry of Technology for 1967-8 show the sort of increases that might be anticipated. Administration charges have shot up to £53 million from £24.4 million with the takeover of the costs of the Ministry of Aviation. Costs of the ministry research establishments have advanced, but unevenly; the National Physical Laboratory and the National Engineering Laboratory are among those which show increases, to £2.5 million and £1 million respectively, but some of the laboratories—the Fire Research Station, Torry Research Station, and the Water Pollution Research Station—show marginal reductions associated with reductions in staff.

The industrial services of the ministry show a considerable increase, from £15.3 million to £24.2 million. The bulk of the increase falls under two headings: research and development contracts, and assistance to the shipbuilding industry, which now represent £6.4 million and £1.9 million respectively. (The shipbuilding figure is part of the Shipbuilding Industry Bill now before Parliament.) Other industrial services, such as the Production Engineering Advisory Service and the Industrial Liaison Service, amount to a further £1.2 million, and purchases of machine tools and similar measures will cost £0.9 million. The grant to the National Research Development Corporation is down, from £7.4 million to £5.5 million, but this is because of a reduced grant for interest relief. The National Computing Centre gets £800,000, against £290,000 last year.

The aerospace section of the ministry shows some changes. Research and development work by industry is down from £190 million to £177.6 million, and the contribution to ELDO falls by £3.3 million to £9.5 million. The cost for the production and development of *Concord* is up by £10 million to £42.2 million, and a further £7 million is needed for the development of other aircraft. Acting as procurement agency for the services, the ministry will spend £366.6 million on aircraft. The Atomic Energy

Fig. 1. Expenditure, Ministry of Technology. Shaded areas, 1966-7; open areas, 1967-8. Sharp increase in administration charges is caused by absorption of the Ministry of Aviation.

Fig. 2. Expenditure by Department of Education and Science on the research councils. Shaded areas, 1966-7; open areas, 1967-8.

Authority shows a marked decrease, from £29 million to £17.5 million. Current expenditure of the authority is down by £7 million to £58.4 million, through substantial reductions in the salary bill and in stores, materials, and services. Income to the authority through sales has increased from £9 million to £14 million.

The Department of Education and Science spends money on research and development directly, as through the research councils, and indirectly in the sense that the grant to the University Grants Committee includes more than £40 million a year which is eventually spent in university laboratories. The department is directly responsible for the British Museum (Natural History) and will spend £0.96 million there in the coming year. The grant to the Royal Society will be £657,000, and spending on what is called scientific and technical documentation £0.37 million. There are also substantial expenditures on the National Lending Library (£681,000), the National Reference Library (£700,000) and the Office of Scientific and Technical Information (£150,000).

The estimate for the University Grants Committee is £236 million, an increase of almost £16 million over last year. Grants for recurrent expenditure are up by about £17 million to £151.4 million, but capital expenditure shows a fall from £77.4 million to £74.9 million. The grants towards the cost of new accommodation in teaching hospitals increase sharply from £2.5 million to £4.1 million. The research councils all show increases in their grants (Fig. 2), and the smaller ones are advancing faster, as would be expected. The Science Research Council, with a budget of £36.5 million, shows only a 7.4 per cent increase, while the Social Science Research Council more than doubles its income to almost £1.2 million.

# British Universities and Government Establishments

Two years ago the Council for Scientific Policy appointed a working party to consider ways of achieving closer collaboration between universities and government establishments. The committee, under Sir Gordon Sutherland, has found the establishments to be more willing partners than the universities.

THE view that government research establishments would welcome a much closer relationship with universities is one of the principal conclusions of the Sutherland committee on liaison between universities and government establishments. The committee, however, is less certain that the universities are ready for a closer relationship. "Opinion is not quite so definite in the universities . . . and at present only a minority of the universities appear to us to be willing to take a strong initiative in this matter." The committee says, by way of oil on potentially troubled waters, that the diffidence of the universities is understandable because the advantages of collaboration are usually more obvious to the government establishments. The committee says that some universities are afraid that their research work would be "weakened" by some of the proposals that it has been discussing.

The Sutherland committee was set up by the Council for Scientific Policy in April 1965. Its members are Sir Gordon Sutherland, Dr. A. H. Cottrell, Professor K. C. Dunham, Professor E. B. Chain, and Professor R. V. Jones. Its scope allowed it to consider practices in all government research establishments, including those of the research councils and the Atomic Energy Authority. The working party set out deliberately to collect information about the degree of collaboration, and in particular circulated a questionnaire to universities, with the collaboration of the University Grants Committee which undertook to solicit replies and analyse them.

## Opportunities

The underlying theme of the report is that there are at present many neglected opportunities for collaboration between government laboratories and universities. It singles out five principal ways in which more might be done—closer staff relationships, co-operative research projects, formal association of research establishments with universities, recognition of establishment research for higher degrees, and easier mobility in transfer for people. Evidently much of what the committee has to say will bear on discussions such as those by which the Fulton Commission will eventually recommend what should be done about the Civil Service.

The committee says that "a considerable majority" of government establishments would like to see some members of their staffs given university status and university titles so that they could spend some of their time lecturing, supervising students and "taking some part in the discussion of university policy on research and advanced teaching". Something along these lines is at present being done at twenty universities, although most existing arrangements are concerned with the staff of research units established by the Agricultural and Medical Research Councils. The committee commends the way in which the universities of Strathclyde and Birmingham have set up close collaboration with the National Engineering Laboratory and the Royal Radar Establishment respectively, says that academic status seems to be a harbinger

of closer collaboration in research, recommends that both universities and government establishments should consider ways of strengthening collaboration, and argues that when new government research establishments are created they should be sited near a suitable university.

On co-operative research projects, the report says that the establishments at present subsidize by means of extramural contracts roughly £1.9 million of research a year in universities. Its enquiries have, however, revealed that universities are usually unwilling to accept these contracts unless they are for work which fits well with research already under way. The committee thinks that there is more that can be done and has apparently been particularly attracted by the way in which the Swedish Government is able to initiate research work at universities in fields of national importance by creating research groups which are in due course taken over by the universities. The committee thinks that government departments must take the initiative in this field and it urges them to make specific proposals for co-operative research projects with appropriate universities.

## Collaboration

A more radical vehicle for collaboration is the formal association of a research establishment with a university. It is particularly attracted by the way in which the United States government has set up research centres near universities and has delegated to the universities responsibility for their operations. The Sutherland committee argues that this arrangement gives university staff and research students a valuable insight into research of national importance without leading to government control of academic research because "participation in the work of the establishment is voluntary". But the Sutherland committee is clearly aware that this is a thorny issue and it recommends that arrangements like these should be studied in greater depth by the Committee of Vice-Chancellors and Principals and by government departments to see whether Britain can make use of precedents established elsewhere. On the awarding of higher degrees, the Sutherland committee points out that there is at present no uniformity of policy among the universities and "even within a single university towards different establishments". It is, however, full of admiration for the way in which the University of London has designed new academic regulations which make it possible for people to read for Ph.D. degrees while working at government establishments. Under the new arrangements, the university is responsible for seeing that supervision is satisfactory, while candidates for higher degrees are given a "real contact" with the university. The committee rejects the fear that an extension of these arrangements to other universities would mean that the universities would be denuded of research students. The argument is that if a student can earn a full-time salary as a member of a research establishment and still read for his degree, he is unlikely to be satisfied with the usual

student's grants. The committee's reason for thinking otherwise is that only a small part of the work at an establishment can lend itself to Ph.D. work, so that the student turned civil servant will nearly always have other things to do. But then there is the problem of writing a thesis in private time, the fact that "the more academically inclined will always prefer to spend all their time in a university", and the fact that government research establishments have a limited capacity to absorb students. Altogether, the committee thinks that the government establishments would not be able to absorb more than 150 potential Ph.D. candidates a year, or less than 7 per cent of those at present graduating with Ph.D.s in science, engineering and technology from British universities.

### Establishments

The argument that scientific people should be able to move more easily from and into government establishments has been a steady chorus for some years now, and the Sutherland committee has lent its own support. It says that pension arrangements are often quite different in the universities and the research establishments, which means that easy movement is discouraged. The committee points out that, elsewhere than in Britain, pension difficulties are a less serious obstacle and it expresses the hope that something will soon be done. The committee also complains that the Civil Service establishments are usually unable to help with removal expenses.

In practice, it seems that the migration of scientists from some parts of the government research machine in Britain is comparatively high. Thus in the five years 1961-65 inclusive, 159 members of the MRC staff, or about 19 per cent of the total, left for university employment. Elsewhere than in the MRC, migration seems to be much less frequent. The government establishments also appear to be able to recruit from the universities, at senior as well as junior grades, scientists whose numbers "almost exactly equal the losses". In the period 1961-65, 346 losses from government establishments to universities were almost exactly cancelled out by 342 recruitments. In practice, however, the MRC appears to be in an especially favoured position and recruited 29 per cent of its total staff from the universities in this period. This implies, of course, that other kinds of public research establishments were less able to recruit from the universities and the committee estimates that only 2.4 per cent of the research staff of other laboratories was obtained by recruitment from the universities in the period of five years.

The enthusiasm of the government departments for closer collaboration is plainly moderated, at least in part, by an awareness of the administrative difficulties thereby entailed. The Ministry of Technology, in its evidence to the Sutherland committee which necessarily refers to the period before amalgamation with the Ministry of Aviation, points out that the ten research stations on its strength would welcome closer association with the universities. Directors of establishments can receive research students without charging the universities for them. The National Physical Laboratory is one example of a laboratory which has undertaken to help neighbouring universities with teaching and which has found the courses provided to be valuable and stimulating for the staff. The United Kingdom Atomic Energy Authority is more free than most public laboratories to make special arrangements with universities and is in the habit of making special facilities such as reactors, accelerators and computers available to university scientists. The Authority says that during the year 1964-65 ten university scientists worked at each of Harwell and Aldermaston on reactors, and that more than 80 scientists from universities were attached to Atomic Energy Authority laboratories for work on accelerators and computers. Altogether the Authority has appointed 140 consultants from 30 universities and has made a number of joint appointments with universities.

The research councils differ not so much in their willingness to collaborate with the universities as in their policy on supporting research. The Medical Research Council, with its device of creating research units which frequently entail joint appointments with the universities, is understandably the most closely embedded in the university system. But the Sutherland committee points out that five of the units and institutes of the Agricultural Research Council do not have arrangements with universities. At present it seems that something like 94 staff members and 135 research students at Agricultural Research Council laboratories are working for Ph.D. degrees.

The service departments are chiefly engaged with the universities by means of research contracts. The Royal Navy does, however, employ 70 university consultants in various ways and the loan of naval survey ships to university oceanographers is one example of collaboration. The Army boasts of relationships with university consultants and students even at the Chemical Defence Experimental Establishment. The Royal Air Force, of course, has the Meteorological Office under its wing and close links with the universities on matters such as meteorological research. The service departments said in their evidence to the Sutherland committee that security need not inhibit relationships with universities in "quite large sectors" of their research activity.

### Universities

The Sutherland committee records somewhat laconically the conflict among the universities on the desirability of training Ph.D. students at government laboratories. Most universities, it appears, have some links with government establishments although geography is frequently against them. Opinion was divided on the desirability of part-time lecturers from government establishments, and three universities (Bristol, Brunel and Wales) say they would prefer full-time teachers to part-time. Altogether it seems that 21 universities are using staff from government establishments for research purposes, while a similar number uses them for teaching as well. Another nine universities use staff from government establishments to provide occasional lecture courses. It seems that all universities allow registered research students to conduct some research at government establishments, but that arrangements vary from place to place and that some residence is usually thought to be necessary. The universities of Birmingham, Bristol and Manchester argued to the committee that candidates reading for a Ph.D. degree should be regarded as trainees in research who require a continuous period of close supervision and help. Manchester emphasized the importance of links between students and fellow research workers, while the Vice-Chancellor of the University of Birmingham (Sir Robert Aitken) was particularly anxious that government establishments might be in a position to "offer the recruitment bait of Ph.D. in addition to the drawing power of a substantial salary and attract potential university students thus prejudicing the future of research within universities".

As a sub-committee of the Council for Scientific Policy, the Sutherland committee cannot have the force of law. Its recommendations will in fact only acquire their full force when a number of other committees have reported on matters such as the mobility of scientific personnel and the loss of trained people from Britain to the United States. Moreover, it is clear that the universities will have to work out some machinery for taking a view on issues such as the proposal that the arrangements in the University of London for Ph.D. students at government establishments should be extended elsewhere. Another issue, not raised by the Sutherland committee but recently made topical by Professor P. M. S. Blackett (*Nature*, 213, 755; 1967), is that of whether the scientific work at present carried out in government establishments should remain there in perpetuity.

# The School Mathematics Project

by  
BRYAN THWAITES

Principal,  
Westfield College,  
University of London

The School Mathematics Project is one of several organizations for the improvement and renewal of parts of the school curriculum in Britain. It is now concerned with problems of application as well as of innovation.

THE School Mathematics Project is now in its sixth year of effort aimed at reforming mathematics in secondary schools. It is the largest of the English reform groups working on secondary mathematics; it is the only one which has already set examinations for the General Certificate of Education at both the Ordinary and Advanced levels according to a radically new course covering, in a continuous fashion, the whole age range of 11–18 years; and it is exerting considerable influence in overseas countries, notably in East Africa where there is an EASMP and in the United States. It is therefore of interest (i) to discuss to what extent the project has been able to fulfil its original objectives, (ii) to examine whether the influence of the project is, on the whole, beneficial both to the course of mathematics itself and to the boys and girls who will have undergone its rigours, and (iii) to have some inkling of the future activities of the project. I would like, in this brief article, to consider these three points in turn and to draw some conclusions.

First, then, to what extent are the original objectives being fulfilled? These objectives were fairly clearly stated in 1961 when the five founders of the project met to plan a co-operative experiment between a number of schools. They were to draw up a mathematical syllabus for grammar schools, and to organize appropriate O- and A-level examinations, so as to reflect, more truly than do the traditional syllabuses, the modern character and usages of mathematics. It was felt at the time, and events have fully justified it, that the most effective way of ensuring that new material is introduced into schools is to arrange for the corresponding examinations. The project has therefore claimed as one of its major achievements the agreement which exists between all the GCE Examining Boards that they should make available to their own schools, and through their own respective organizations, the special SMP examinations. The co-ordinator of this scheme is Mr. A. E. E. McKenzie of the Oxford and Cambridge Schools Examination Board, Trumpington Street, Cambridge (to whom all formal queries about the examination arrangements should be addressed).

## Growth

The effectiveness of this approach can be judged from the following figures for the candidates for the SMP O-level examination:

1964	1965	1966	1967 (est.)	1970 (est.)
919	1,548	3,526	7,000	60,000

These may be compared with the national total of O-level mathematics candidates which, in 1966, was 204,000.

As to the content of the GCE syllabuses, the evangelistic role is no longer necessary for any of the reform groups, because the need for a change from the traditional syllabuses is now generally accepted both in the United Kingdom and abroad. At O-level, there is a broad consensus of opinion in this country as to the desirable

directions to take. Thus, for example, the O-level course proposed by the Midlands Mathematics Experiment (directed by Mr. Cyril S. Hope of the Worcester Training College) contains much the same material as the SMP's course (except for its notable inclusion of some elementary calculus treated in a rather traditional way) as does also the Scottish Mathematics Experiment organized by the Scottish Education Department.

## Content

All these O-level syllabuses emphasize the nature of number, and the fundamental properties of the ordinary arithmetic operations on the real numbers; and for this and other purposes, they introduce the notion of sets and the operations on sets, with simple applications of these outside the field of real numbers. Geometry is treated in a more intuitive fashion than is traditional and, although the usual Euclidean theorems are recognized as containing much useful general knowledge, boys and girls are not trained nowadays to produce proofs of theorems or riders which are rigorous according to conventional Euclidean methods. The SMP has paid special attention to geometry and has produced "elementary-geometry from an advanced standpoint" by studying plane geometry principally through the medium of the plane transformations. This approach to geometry has, in the SMP's view, some decisive mathematical advantages, not least of which is the consequence that much of algebra and geometry can then be unified in such a way as to teach the underlying structure and wide applicability of certain mathematical systems.

If these exemplify some of the major innovations introduced into the SMP syllabus, there are many more which ensure that the syllabus represents a major step away from the traditional, as very many parents, in trying to help their children with homework, have found to their cost. At O-level, therefore, the organizers of the project think that it is certainly well on towards reaching its original objectives.

A-level, however, is rather a different proposition. For one thing, there are many more external constraints on a sixth-form course than on an O-level course. One major constraint arises from the use made of the A-level examination as a university entrance examination rather than its proper use as a school-leaving examination. This means that university departments of all kinds—ranging nowadays from departments of mathematics to those of biology or economics—can impose their demands (however implicitly or unconsciously) on the A-level syllabus. Again, pupils themselves, in their half-role of consumer, are unwilling to accept without misgiving a sixth-form course which lays greater stress on the study of a subject for its own sake than on its usefulness as a qualification in their later careers. Then there is the very difficult problem of the time allowed for mathematics in the sixth form; the amount of mathematics which can be done—and especially of "new" mathematics, because there is at this level a basic amount of manipulative mathematics

which is almost bound to be included—obviously depends on whether seven, ten or fourteen teaching periods a week are set aside for mathematics. And the final major problem concerns the character of mathematics at the sixth-form level; in particular, should mathematics remain the kind of unity which is accepted and indeed urged at O-level, or should it be split up into identifiable parts such as pure, applied, statistics, computation, mechanics, and so on?

### Time

The School Mathematics Project has, it is reckoned, devoted some 10 man-years, all told, to these problems of the sixth form in an intensive effort to solve them in a practical form by the production of syllabuses, texts and examinations which, it was hoped, would meet with general approval. In this effort, there have been very wide consultations within the world of mathematics; in particular, very specific consultations took place with university departments of mathematics, as a result of which a lengthy report was published as an appendix to the 1963/64 *Director's Report*\*.

All this effort has been a failure in the sense that not everyone is equally enthusiastic about the A-level solution produced by the SMP. Broadly, this solution is a "core" syllabus (leading to a single subject A-level) which is a unified treatment of what is considered to be absolutely necessary for sixth form mathematics; then, in addition, there is an optional "Further Mathematics" syllabus (again regarded as a unified body of mathematics, and also a single subject A-level) for those sixth formers who, for any reason, may wish to devote more of their time to mathematics. Members of the SMP are, of course, convinced of the soundness of their solution, and they particularly welcome the movement which the Schools Council seems to be taking towards one major subject in mathematics together with a number of optional minor subjects, because they feel that the SMP course is ideally suited to just such a development.

Readers may be interested to judge for themselves the worth of some of the "new" type of questions at A-level which the SMP is now producing. The following examples are taken from the July 1966 examination:

Show that the set of matrices of the form

$$\begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}$$

is closed under the operation of matrix multiplication.

This question combines experience of matrices as tools with an appreciation of structure of mathematical systems.

$$"x \text{ real} \Rightarrow (x^2 > 1 \Rightarrow x > 1)."$$

Is this assertion true or false? If it is true, prove it; if it is false, give a counter example.

This places great emphasis on precision of thought.

Use a step-by-step method, with 0.2 as the step-length, to estimate the value of  $y(1)$ , given that

$$dy/dx = 1 + y^2, \text{ and } y(0) = 0.$$

Lay your work out in tabular form after the pattern:

$x$	$y$	$y^2$	$1 + y^2$	$\Delta y$
0	0	0	1	0.2
0.2				

Compare your value of  $y(1)$  with the exact value.

This example illustrates the importance which the SMP attaches to computers and their potentialities, and to the ideas of approximation. Flow diagrams form an inherent part of the SMP teaching.

Early experimenters on the flow of fluids through capillary tubes proposed a formula of the form

$$Q \propto \frac{1}{\mu} \left( \frac{dp}{dx} \right) r^n$$

where  $Q$  is the volume flow per unit time

$\mu$  is the coefficient of viscosity (of dimensions  $ML^{-1}T^{-1}$ )

$dp/dx$  is the pressure gradient along the tube

$r$  is the radius of the tube, and

$n$  is a numerical index to be found.

Suggest a suitable value for  $n$ .

This is a question which illustrates the attitude of the SMP to mechanics, namely that a qualitative appreciation of a physical situation, and the ability to formulate a mathematical model of it, are more valuable assets to a pupil than the capability of manipulating the standard forms of Newton's second law for highly idealized situations.

### Future

These four examples will give readers an inkling of the objectives of the SMP; the *Report* for 1965/66 reprints the 1966 A-level examinations *in toto* and will repay further study.

We must now return to the two remaining aspects of the SMP's work mentioned in the first paragraph of this article. As to the influence, so far, of the SMP's work on schools, one can only judge from the subjective reports which flow in from schools and also sometimes from pupils. It seems beyond question that, over the past five years, something of a revolution has taken place in our schools as to the atmosphere and morale in the mathematical classroom and as to the teaching techniques now exploited by mathematics teachers. The SMP can claim only a very small part of the credit for this, for it is an effect wrought by many individuals and organizations. The Nuffield work (directed by Dr. G. Matthews, Nuffield Lodge, Regent's Park, London, N.W.1) at the primary level should be mentioned together with that of people such as Miss E. Biggs of the Department of Education and Science and of organizations such as the Mathematical Association. But the SMP has played a particularly vital part at the secondary level by providing teachers with both the texts to get their teeth into and the teaching conferences for in-service training aimed directly and the most helpfully at a specific course.

As to the future of this particular project, it is now clear that the SMP has set itself on a road to which there is no end. Its English team now consists of some sixty mathematicians who work in an entirely voluntary association with an immense and untiring enthusiasm. Their work has spread across the world and has inspired other voluntary teams to form overseas under the same banner. So long as there is vitality and enthusiasm, so long will the SMP continue to push on in the vanguard of mathematical reform. The first wave of reform, started possibly by American groups in the early nineteen-fifties, is now nearly complete. The work done during this first wave now needs consolidating in the many hundreds of secondary schools which are now teaching "new" material of one kind or another; and this consolidation is best left to the long established organizations, such as the university institutes of education, which have deep experience of such work. The time has now come, however, for the second wave to be initiated, and it is to this task that the energy and resources of the SMP will soon be directed.

\* These comprehensive *Reports* can be obtained, annually, from the SMP Office at Westfield College, University of London, London, N.W.3.

## BOOK REVIEWS

## ATOMS FOR STUARTS

Atomism in England from Harriot to Newton

By Robert Hugh Kargon. Pp. viii+168. (Oxford: Clarendon Press; London: Oxford University Press, 1966.) 42s. net.

SINCE Kurd Lasswitz's pioneering study of the *Geschichte der Atomistik* appeared in 1890 our knowledge of atomic theories in the post-Renaissance period has grown rapidly. The corpuscularian ideas of Descartes and Gassend in France and Hobbes, Boyle and Newton in England, in particular, have been the subject of intensive research. Most scholars have followed Lasswitz's internalist approach, treating the development of atomism as essentially the interplay of explanatory ideas put forward by a few great scientists, wholly divorced from the social, political and theological realities of their age. By ruthless chopping of contrary fact a simple picture of the growth of atomism in the seventeenth century can be drawn: this sees the scientists of the period, in reaction against the stilted, imprecise, categorized qualities of mediaeval aristotelianism, as irresistibly attracted to the vivid, quantitative, open-ended explanations afforded by models of small, hard, "massy" bodies in motion. In Kargon's present view such an idealized portrait is both ahistorical and inadequate: to gain a balanced insight into the historical part played by atomist theories of matter in England in the Stuart period it is necessary not only to take account of the many secondary figures responsible for the acceptance and dissemination of the ideas proposed by the gifted few, but also to assess the cultural milieu in which they lived.

In his book Kargon has not always succeeded in integrating these opposed internalist and externalist attitudes, and too often it is difficult to seize the essence of a particular scientist's atomic point of view through a blurring fog of historical detail. Certainly, his close-knit narrative communicates an immense amount of unfamiliar information. In step with the recent revival of interest in this long underestimated Elizabethan giant, we are urged to look on Thomas Harriot as the father of English atomism even though his influence was virtually restricted to his friends Torporley and Warner. Thereafter in quick succession we are given a summary of Bacon's early atomistic views and a condensed account of the Gassendist revival of Epicurean atomism (introduced into England by Hobbes, Digby, Cavendish and especially Walter Charleton), while the concurrent impact of Cartesian mechanical philosophy is traced in the writings of Robert Boyle, Isaac Barrow and Newton. It is less easy to identify general conclusions in this mass of narrowly documented if not wholly pertinent detail, but he asserts sensibly that, because Greek atomistic ideas were too closely involved in philosophical dispute over the existence of the "indivisibly" small to be a viable basis for quantitative explanation, not till a kinematics (and indeed dynamics) of the motion and impact of bodies had been formulated was it possible to have a physically useful atomic model. Disappointingly there is not a single diagram in the book—he gives no examples of how individual atomists differed

in their technical accounts of such intractable phenomena as the simultaneous reflexion and refraction of light at an interface, the shapes of crystals or gravity. The vulnerability of atomism in the early century to the popular charge of being intrinsically pagan and so atheistic is stressed, while Bacon and Barrow are provocatively cited as the sources for Newton's concept of hypothetical method, but many readers will find that this book's real value is in its excellent bibliography.

D. T. WHITESIDE

## EDITORS WANTED

## Chymia

Annual Studies in the History of Chemistry, Vol. II. Edited by Henry M. Leicester. Pp. 208. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1966.) 40s. net.

THE most interesting paper in this volume is that by J. B. Phillips, *Liebig and Kolbe, Critical Editors*. This is the sort of historical essay which has something useful to say to any practising chemist of today; in this case, about the assessment and communication of research. It is doubly interesting because it makes one ask: how critical are the editors of *Chymia*?

The other twelve papers vary remarkably in merit. The extended view is taken by N. A. Figourovskii, who does his fellow historians of other countries a substantial service by a detailed study of *Chemistry in Early Russia*. In contrast, a single instructive episode is described, with his usual lucidity, by W. A. Smeaton (*Macquer on the Composition of Metals*). V. M. Schelar, in a well organized account of the origin of the third law of thermodynamics, faces up bravely to a topic which the average historian of chemistry passes fearfully by.

One would rightly expect any editor to welcome these papers as they stand, but not that of W. D. Miles on the European travels of J. C. Booth, the American consulting analyst. This pedestrian selection of extracts from a manuscript diary ends with a quotation from Edgar Fahs Smith: "[Booth's] idea was that the laboratory should be a miniature factory and the factory a mammoth laboratory". Had this quotation come first and been used as a guiding light for the interpretation of the diary extracts, Miles could have produced a paper of far greater value. It is an editor's duty to try to draw out of a writer the best that is in him, to be constructively critical, which could have been done in this case.

The same failure of constructive editorship is to be seen in the paper by N. L. Jain on *Chemical Theories of the Jains*, which contains, for example, confused references to "electrical properties of substances" at a period apparently (it is not at all clear) around the first century A.D. when there were no electrical concepts of the sort used in the context. Again: "The atoms have Brownian movement. This makes the atoms dynamic rather than static. This movement may be due to natural or internal causes or to external forces. Sometimes this may be so vigorous that the atoms traverse the whole universe in a moment". What justification is there for calling a random motion of this vague sort a "Brownian movement"? The matter theories of other periods or cultures can be very interesting, but no service is done to their study when insufficient effort is made to protect the reader from confusion with modern concepts or terminology.

If the editors of *Chymia* expect its papers to have style and substance, they could surely, with their great experience, guide their contributors into tidier writing and clearer thinking. Liebig and Kolbe may have overstepped the mark at times, but it would be better for the editors of *Chymia* to take this risk rather than that of allowing *Chymia's* good reputation to decline.

F. GREENAWAY

## RADAR CONTINUED

### Radar Techniques for Detection, Tracking and Navigation

Edited by W. T. Blackband. (Proceedings of the 8th Symposium of the AGARD Avionics Panel, London, September 21-25, 1964.) Pp. viii+608. (New York and London: Gordon and Breach, 1966. Distributed in the U.K. by Blackie and Sons, Ltd.) \$37.50.

ONE of the useful organizations which has stemmed from NATO has been the Advisory Group on Aeronautical Research and Development (AGARD). This organization covers the usual fields of aeronautical research including aerodynamics and propulsion, and also includes in its activities that broad field of ancillary devices which is loosely termed "Avionics". AGARD takes the realistic view that electronic devices are essential elements of any airborne vehicle whether it is to be used for military or civil purposes.

Over the years AGARD has held a number of symposia which have been devoted to various aspects of the avionic field, and the present volume covers such a meeting which was held in September 1964 and which was devoted to the themes of radar techniques for detection, tracking and navigation. This volume consists of thirty-one papers which have been written by engineers and scientists active in the field of radar who are working in government, university or industrial research laboratories located in the various NATO countries.

Clutter is still the principal enemy of radar system designers and a number of papers in the present volume are concerned with the modulation problem and of how radar systems can be devised which will provide methods of enhancing the probability of detecting moving targets in the presence of clutter. The technique of pulse compression is described; frequency modulation is employed within the pulse together with a dispersive line in the receiver system which provides time delay varying with the frequency. In this way the effective pulse length of the radar can be compressed to 1/1000th of the transmitted pulse and resolution improved accordingly.

A number of the authors recognize that the target itself can materially affect the nature of the reflected signal. This interaction may prejudice radar detection on the one hand, but it can also provide information about the target which can be extracted by appropriate signal processing. This kind of study has been applied to the examination of the radar echoes from the planets, designated somewhat quaintly as "unco-operative targets", the non-co-operation arising from the remoteness of these bodies and the nature of their reflecting surfaces. It is very impressive to read that the power density of the radar echo from Venus at its apogee is  $3 \times 10^{-25}$  W. Radar echoes from extended scatterers have also been considered by a number of authors, and these papers include careful examination of the nature of ground returns, Doppler navigation, ground mapping and also the applications of radar to meteorology.

Although a number of the papers deal with the advanced theory of radar systems and the nature of radar information, the techniques of radar are not neglected, and improvements in transmitters, frequency and phase scanning arrays are dealt with.

It is probably true to say that even during the war years the main difficulty was not so much the collection of radar information as the ability to analyse and present the information contained in the echo signals. Some of the papers show very clearly that the emergence of a new electronics, based on solid state devices, is providing the means for the storage and analysis of radar information on a scale, and with a wealth of detail, which greatly transcends anything that was possible during the war. The application of computers operated in the real time mode permits executive commands to be extracted from

this body of information and used for the purpose of aircraft control in both the civil and military case.

It is clear from this volume that radar research and development is still very active indeed, and that methods of radar monitoring the air space have become most subtle. Although the papers in a collection such as this are bound to be somewhat uneven, they never fail to be exciting and interesting, and the book may be taken as a good presentation of radar developments which have taken place during the past ten years. The complexity of radar equipment is now so great, and the time scale of development so long, that although two years have passed since the AGARD conference that prompted these papers the book is still up to date and will be of great value to radar research men for some years to come. E. EASTWOOD

## SINGULAR WAVES

### The Plane Wave Spectrum Representation of Electromagnetic Fields

By P. C. Clemmow. (International Series of Monographs in Electromagnetic Waves, Vol. 12.) Pp. vii 184. (Oxford, London and New York: Pergamon Press, Ltd., 1966.) 50s. net.

IN 1919 Weyl published the formula

$$2\pi \frac{\exp\{ikR\}}{ikR} = \int_0^{2\pi} d\varphi \int_L \exp\{ik(\alpha x + \beta y + \gamma z)\} \sin\theta d\theta$$

valid for  $z > 0$ ,  $\varphi, \theta$  being the polar angles of the unit vector  $(\alpha, \beta, \gamma)$  referred to the  $z$ -axis,  $R^2 = x^2 + y^2 + z^2$ , and  $L$  a certain path of integration in the complex  $\theta$ -plane. He thereby obtained the plane wave representation of a singular solution of the wave equation in the presence of a point source at the co-ordinate origin. The superposition involves inhomogeneous plane waves or alternatively plane waves travelling along imaginary directions, and Weyl's step is crucial in obtaining an expansion or representation theorem involving plane waves for general electromagnetic fields generated by sources or bounded by surfaces. This theorem received little attention—it is not mentioned in the older textbooks—until soon after the Second World War when Brooker and Clemmow took up the idea. In two classic papers they demonstrated the application of the angular spectrum of plane waves to radio propagation over flat surfaces, to certain aerial problems and to diffraction theory. Soon afterwards, Clemmow obtained the exact solution of a wide class of two-dimensional diffraction problems and there have been other applications since then.

Dr. Clemmow has now written a connected introduction to the subject. It is a most beautiful book and will surely become a classic in its field. Maxwell's equations in M.K.S. units and the idea of induced electric and magnetic surface current densities are of course assumed to be familiar, and the reader must be at home in the complex plane, but that is all that is required. A self-contained and careful exposition establishes, for example, the plane wave representation, its relation to other representations and the way to separate off the field in the radiation zone. Then the applications are considered. These cover diffraction by a plane screen, propagation over plane surfaces, the fields of point particles, both synchrotron radiation and the Čerenkov radiation and finally sources in anisotropic media. There is a very satisfying demonstration of the optical theorem and Babinet's principle.

The text is completely self-contained; there is not a single reference to other material or authors, and Dr. Clemmow is too modest to mention his own contributions to the subject. He clearly enjoyed writing the book, and I enjoyed reading it. It can be most warmly recommended, not only to students of electromagnetic theory but to everybody concerned with scattering problems. S. ZIENAU

## INTEGRALS AND SYMMETRY

### Homology and Feynman Integrals

By Rudolph C. Hwa and Vigdor L. Teplitz. (Mathematical Physics Monograph Series.) Pp. xi+331. (New York and Amsterdam: W. A. Benjamin, Inc., 1966.) n.p.

### Unitary Symmetries and their Application to High Energy Physics

By M. Gourdin. Pp. xi+303. (Amsterdam: North-Holland Publishing Company, 1967.) 86s.

(1) ANALYTIC properties of collision amplitudes play a central part in the study of strong interactions of elementary particles. Some of these properties can be derived rigorously from quantum field theory and some can be obtained from an axiomatic approach to  $S$  matrix theory. By far the largest amount of information about analyticity has been obtained, however, from the study of Feynman integrals in perturbation series for collision amplitudes. The basis of the approach is due to Cauchy, whose theorem on complex integration provides a method for the analytic continuation of Feynman integrals as functions of the relativistically invariant energies that describe the collision. This method fails when singularities of the integrand cannot be avoided by the contour of integration, and this may be a singularity of the Feynman integral. When there are several complex variables of integration, it is difficult to ascertain whether singularities of the integrand actually meet the (several dimensional) contour of integration so as to make the Feynman integral singular. This difficulty provided the motivation for developing and applying homology to Feynman integrals.

In this book the authors first describe the classical methods of studying the problem that are based on what a physicist would regard as the obvious extensions of Cauchy's theorem. They then outline homology theory and show how it converts the problem of the geometry of Feynman integrals into an algebraic problem. Their account of the theory is a valuable addition to the reprints of some of the main papers on this subject that are included in the second half of the book.

The book is recommended for graduate students in theoretical physics who have strong mathematical interests and abilities.

(2) The importance of the unitary group  $SU(3)$  for describing the symmetries of elementary particles was recognized very soon after the classic papers written in 1961 by Gell-Mann and by Ne'eman. Subsequent generalizations have encountered difficulties in formulating symmetries in a fully relativistic manner, but various procedures have been established, based on an algebra of currents that incorporate both angular momentum symmetries and  $SU(3)$  symmetries.

The first two-thirds of *Unitary Symmetries and their Application to High Energy Physics* presents a mathematical description of the physics of symmetries. It begins with the essential features of Lie groups and the classification of the strongly interacting particles using the group  $SU(3)$ . This is followed by applications to strong, electromagnetic and weak interactions. The group  $SU(6)$  is then introduced and some of its consequences are investigated. There is a chapter on current algebra, but this covers only a small fraction of the very extensive literature on the subject that has appeared in the past eighteen months.

The last third of the book describes the mathematical formulation of Lie groups and Lie algebras. It is likely that an increasingly important part in the theory of elementary particles will be played by Lie groups. This book is a good introduction to the subject of Lie groups and elementary particles at a level that is suitable for graduate students in theoretical physics.

R. J. EDEN

## MORE GAS FOR BURNING

### Natural Gas

A Study. By E. N. Tiratsoo with an Introduction by Sir Harold Hartley. Pp. xvi+386. (London: Scientific Press, Ltd., 1967.) 70s.

THE publication of this excellent and comprehensive study on natural gas is greatly to be welcomed. The author is a geologist, but he has successfully "tried to widen the scope and interest of the book for the non-geological reader by including chapters on utilization and transportation, as well as an historical background". In fact, there is hardly an aspect of this great field of human endeavour on which the author has failed to provide more complete and significant information than has hitherto been conveniently available. The British reader, thrilled with the discovery of important natural gas reserves in the North Sea Continental Shelf, will perhaps be particularly grateful for chapters eleven to sixteen which deal with the methods of locating, measuring and exploiting gas reserves; the transportation and storage of gas; and the uses of natural gas and the economic considerations involved, with particular reference to the problem of converting the existing distribution system and burning appliances to the new fuel. "The problems of conversion for 12-13 million households are obviously formidable, and much depends on the composition of the natural gas to be used." As these problems are described by the author, it becomes very clear that the amount of natural gas likely to be used in Britain in, say, 1970-36 months from now—will depend primarily on the speed at which conversions can be carried out and new uses developed, and only secondarily on the quantity of gas reserves found. The Canvey Island conversions, an experimental enterprise on a small scale in a community conveniently isolated from other gas users and close to the methane terminal, have shown that it is not an easy matter to get the thing right, so that the consumer is really satisfied, and the idea that conversions at the rate of 600,000 to 1,200,000 per annum could be achieved in the near future will have to be treated with some caution.

The author's discussion of the problems of leakage, pipe failures and gas-borne dust, which arise when natural gas at high pressures is sent through old low-pressure coal gas distribution systems, is extraordinarily interesting and of the greatest practical importance, and so is his analysis of the storage and transportation problems. No one concerned with national fuel policy matters in Britain or abroad will fail to be grateful to Dr. Tiratsoo for placing his encyclopaedic knowledge at their disposal.

E. F. SCHUMACHER

## VOLCANIC ROCK IN RUSSIA

### Tufflavas and Ignimbrites

A Survey of Soviet Studies. Edited by Earl F. Cook. Translated from the Russian by Miriam Carty. Pp. xii+212. (New York: American Elsevier Publishing Company, Inc.; London: Elsevier Publishing Company, Ltd., 1966.) 60s.

IGNIMBRITES include the most impressive rock-bodies that volcanoes are capable of producing. The largest are the consequence of gigantic eruptions during which, in the space perhaps of hours or days, tens or hundreds of cubic kilometres of rock-melt are converted to small fragments which flow as a turbulent suspension in gas away from the volcano. The flow incinerates, and the resulting deposit buries, everything over an area that can be measured in thousands of square kilometres, and in

the deposit the fragments are often welded together to form a rock as tough as a lava flow. Ignimbrites are widely distributed, and it is clear from this book that they are not lacking in the Soviet Union.

*Tufflavas and Ignimbrites* is a collection of thirty papers by Soviet geologists, presented at a symposium on the subject in Moscow in 1961. The first part, devoted to general problems of tufflavas and ignimbrites including their genesis, begins with a review, specially revised and brought up to date by the Soviet volcanologist, V. I. Vlodavetz. Tufflavas are described as resembling ignimbrites in that they contain rock-fragments, but they differ from them in having a homogeneous lava base and a somewhat different origin. The papers in the second part of the book describe many different occurrences, ranging in age from Cambrian to Pleistocene and in geographic position across the continent of Asia (a map at the front of the book locates the occurrences). The third part discusses aspects of the economic geology of ignimbrites, such as their use as building stones.

This is a book for the specialist rather than the general reader. It is a useful addition to the literature on the subject, and will give both an insight into the development of ideas in the Soviet Union and an introduction to new occurrences from the Caucasus and Kazakhstan to Kamchatka.

G. P. L. WALKER

## GEOLOGY IN THE SOUTH-EAST

### Geology of the Country around Canterbury and Folkestone

By J. G. O. Smart, G. Bisson and B. C. Worssam, with Chapters on Palaeontology of the Gault by R. Casey, and on Palaeontology of the Chalk by R. V. Melville, and other contributions by P. A. Sabine, M. Mitchell, G. P. Jones and H. A. Hope Macdonald. (Memoirs of the Geological Survey of Great Britain—England and Wales.) Pp. x + 337 + 6 plates. (London: H.M.S.O., 1966.) 70s. net.

ONE tends to think of the Victorian geologist as a person who, filled with awe at the mysteries of nature, carefully recorded the details of rocks before him without showing any intellectual curiosity towards them. This approach is still followed by the Geological Survey, and is manifested in its publications. The memoir on the country around Canterbury and Folkestone is no exception. As a report it embodies the worst features of reports: dullness, reiteration, and lengthy lists of irrelevant or trivial information. There are several reviews of the literature which only duplicate the information available in the bibliography, while many topics have an introduction, a general account, and then a detailed account. These accounts are always in text form although much of the information could be better presented diagrammatically.

Because the memoir has many authors it is inevitably patchy—thus the section on the Coal Measures is better than those on the Old Red Sandstone and the Lower Carboniferous because it takes account of modern sedimentological work. Given that this memoir is in the style of previous memoirs the major criticism that can be levelled at it is that it deals insufficiently with sedimentology and overmuch with the palaeontology in the general text. The only serious petrologic investigations reported are those on brick-earths and clay with flints—both in the Recent section. The work on the Recent section is good and is one redeeming feature of the book.

Considering the major contribution that Percy Allen has made to our understanding of the geology of the Weald, much more prominence than one short paragraph should have been given to his work. Casey's work is better represented (possibly because Casey is one of the occasional authors) and his chapter on the palaeontology of the

Gault contrasts in liveliness with Melville's chapter on the palaeontology of the chalk, which is little more than a list of fossils and a few words on the problems of zonation.

If the memoir functions largely as a local geology book then at 70s. it is too expensive. It is true that the detailed descriptions are very much better than the more general passages in this work, but this is only because the general accounts are so bad. The Survey could easily reduce the memoir to a half or two-thirds its present length by re-writing the general sections and replacing much of the detail by diagrams. Let us hope the new director of the Survey will see the reformation of the memoirs as one of his first duties.

## BIOLOGY OF SKIN CANCER

### Carcinogenesis

Edited by William Montagna and Richard L. Dobson. (Proceedings of a Symposium on the Biology of Skin held at the University of Oregon Medical School, 1965.) (Advances in Biology of Skin, Vol. 7.) Pp. xiii + 358. (Oxford, London and New York: Pergamon Press, Ltd., 1966.) 110s. net.

THE seventh volume in the series *Advances in Biology of Skin*, edited by W. Montagna and R. Dobson, contains a series of papers on skin carcinogenesis presented at a symposium in April 1965. The book begins with three chapters on tissue homeostasis. Although cancer constitutes a failure in homeostasis, only in recent years, with the work on gene control<sup>1</sup> and on histones<sup>2</sup>, has much attention been turned to the study of normal control mechanisms. W. S. Bullough and E. B. Laurence's contribution in this field concerns the combined role of tissue-specific chalones (mitotic inhibitors synthesized by cells) and adrenal stress hormones in the control of epidermal cell mitosis<sup>3</sup>. O. H. Iversen, who recently confirmed the existence of epidermo-specific chalones<sup>4</sup>, discusses the kinetics of the reaction of mouse epidermis to chemical carcinogens and other irritants. Whereas other workers (particularly those anxious to find a quick-screening test for carcinogens) have stressed the dissimilarities between the response of the skin to carcinogenic and non-carcinogenic hyperplasia-producing irritants, Iversen concludes that the dynamics of the responses to single applications of the two are similar. This similarity, however, does not apply to the repeated application of carcinogens. In the latter case, cell loss becomes progressively less after each application, which suggests the acquisition by cells of an increasing capacity to resist damage from the carcinogen. T. S. Argyris continues the same general theme by discussing the induction of proliferation in normal tissues by substances derived from tumours, and the relationship between such substances and embryonic inducers<sup>5,6</sup>. The best example of such a substance is the nerve growth factor (NGF) of Cohen and Levi-Montalcini<sup>7</sup>, a protein isolated from the microsomal fraction of a transplantable mouse tumour which stimulates the growth of chick embryonic ganglia in tissue culture. A further recent development in this field is the isolation of an epidermal growth factor (EGF) from NGF (ref. 8). It would be interesting to see the relation, if any, between EGF and the chalones referred to previously.

H. Kirkman discusses the role of sex hormones in hair follicle tumorigenesis (chaetepithelioma induction) with particular reference to the scent gland of the Syrian hamster; and A. W. Horton, P. A. van Dreal and E. L. Bingham put forward the theory that certain long chain hydrocarbons accelerate (promote), and certain polycycloparaffinic compounds delay, carcinogenesis by an effect on the immune response. The evidence for this interesting theory is indirect and corroboration is certainly

necessary because others have shown that gross interference with immune competence, as by neonatal thymectomy, has only a modest enhancing effect on tumour-induction by carcinogenic polycyclic hydrocarbons<sup>9,10</sup>.

It has been known for a long time that exposure to ultra-violet radiation predisposes to skin cancer in man. F. Urbach, R. E. Davies and P. D. Forbes (Philadelphia) review the evidence for the cause and effect relationship. In particular, they distinguish between surfaces which absorb and those which reflect ultra-violet radiation and the significance of reflected radiation in the genesis of cancer. They suggest that whereas ultra-violet radiation may be the sole cause of squamous carcinoma, a second factor is probably involved in the genesis of basal cell carcinoma. J. H. Epstein (San Francisco) describes the induction of skin cancers in hairless mice by irradiation with wavelengths in excess of 3200 Å: rays of these longer wavelengths, which are normally erythrogenic, may induce cancer in the presence of photo-sensitizers with particular action spectra.

Other chapters are concerned with the malignancy of adrenal tumours (H. Pinkus, Detroit, Michigan), the relation between phenotype and susceptibility to particular histological types of skin cancer (G. A. Gellin, A. W. Kopf and L. Garfinkel, New York, N.Y.) and the induction of skin cancer in Simian primates (R. L. Dobson and J. S. Pinto, Portland, Oregon).

As in all books which consist of several invited contributions, the quality and value of chapters vary widely. Apart from this limitation the book is well edited, well illustrated and well produced. F. J. C. ROE

respectively, to features with an appropriate extent in the horizontal or vertical direction. He proposes that the subsequent routing of the output of one of these cells is controlled by one or more "memory" cells, each of which has the ability, probably in an all-or-none way, to close one output route. The reader must refer to the book for details. My feeling is that the idea is interesting and not impossible, but that much more discussion could be given of the possible physiological basis and also how the networks given (for example on page 40), which consist of but a few cells, are supposed to be integrated into the overall nervous activity in the brain.

A great deal of use is made in the book of words taken from outside biology, especially from computing. I belong among those who (page 12) "think that it would be wiser to avoid the computer language in neurology". The difficulty, it seems to me, is that if words such as "code", "store" and "address" are precisely defined in terms of nerve cells, their connexions and firing patterns, then one is not merely using a new language but is making a definite hypothesis about brain function. If, as in this book, they are incompletely defined, then it is often difficult to discover the meanings of sentences in which they occur. I am constantly coming up against problems like that presented by page 19 where "representation" is stated to be a much stronger term than "engram", yet they seem to mean the same thing. Then again, I am worried by the remark on the preceding page about biochemists searching for codes and finding them in DNA. It gives a totally false impression of the development of molecular biology. DNA and its hereditary significance were known before there was any "search for codes". The only such search was for the genetic code. It is true that this was often referred to as the "coding problem" but only as a convenient shorthand, and knowledge of communication theory played no part whatsoever in its solution. The problem was to find the rules of translation between two types of linear sequence the components of which were already known. There can be, as yet, no equivalent search relating to memory (see page 18). Similar matters arise in many parts of the book and the result is that I find it unnecessarily obscure. This is a pity because it contains a great many interesting observations and ideas.

J. S. GRIFFITH

## HOW TO REMEMBER

### The Memory System of the Brain

By J. Z. Young. Pp. vi+128. (London: Oxford University Press, 1966.) 28s. net.

THIS book contains a slightly revised version of the Hitchcock lectures delivered by J. Z. Young at the University of California in 1964. It could serve equally as a summary of, or an introduction to, the extensive experiments on the octopus by Young and his colleagues and Young's views on the nature of the changes accompanying learning. As Young has constantly emphasized, it is very desirable for those of us who are primarily interested in mammalian brains to pay close attention to the results obtained from work on one of the most highly intelligent invertebrates. The octopus, having evolved its brain independently of the mammals, gives us a very interesting example with which to compare and contrast the latter. In particular, its memory is physically divided—matters concerned with vision are stored in quite separate places from those concerned with touch. There does not seem to be any parallel to this in the mammalian brain.

Young draws attention to the numerous cells in the optic lobes, which typically have dendritic fields oriented horizontally or vertically and which he believes to respond,

## HOW TO SEE

### The Functional Organization of the Compound Eye

Edited by C. G. Bernhard. (Proceedings of the International Symposium held in Stockholm, October 1965.) (Wenner-Gren Centre International Symposium Series, Vol. 7.) Pp. xiii+591. (Oxford, London and New York: Pergamon Press, Ltd., 1966.) 126s. net.

THE meetings between Jan Swammerdam and Antoni van Leeuwenhoek in 1674, during which it is probable that they discussed the image-forming properties of the faceted eye, prompted Chairman C. G. Bernhard in his opening address to suggest that the meeting that this book reports might aptly be called the Second Symposium on the Compound Eye.

The subject matter of the book is divided into four parts. The first is concerned with optics and the control of light admission; the second with rhabdom structure, photochemistry, colour discrimination, and reaction to polarized light; the third with receptor excitation and quantum sensitivity; and the fourth with integration of the visual output. An author index is provided, but there is no subject index.

According to Müller's "mosaic" theory, which receives most support from behavioural experiments with arthropods, the functional unit of the faceted eye is the om-

matidium. The ommatidium, however, contains a number of long reticular cells (usually seven or eight) which continue through the basilar membrane as primary visual axons. Evidence is presented by a number of contributors that the image formed by the corneal facet and the cone can be analysed by these sense cells. Thus, Burt and Catton consider that the separation of the rhabdomeres (the inner aspects) of the reticular cells is adequate to resolve diffraction patterns which, as they point out, are imaged at three levels. These images offer little basis for form vision, and are considered to mediate sensitivity to movement. This, in their view, leaves the eccentric cell in each ommatidium with the task of assessing the average illumination entering each facet, thus providing a basis for the mosaic theory.

The inner aspects of the retinulae form the photo-sensitive rhabdom. This is generally supposed to be the site of visual pigment and, from its coaxial location in the light path and from its fine structure—an organized lipoprotein membrane system—it is analogous to the outer segment of the vertebrate receptor cell. Eguchi and Waterman in their analysis of the fine structure of the crustacean rhabdom provide anatomical evidence of a two-channel system for the discrimination of linearly polarized light, and Waterman also contributes a study of polarotaxis and photoreception in crustacea.

Physiological and photochemical aspects of visual excitation are considered by Goldsmith and Fernandez in a review that also lists all available information on the properties of crustacean visual pigments. Electrophysiological studies in the *Apis* drone during light- and dark-adaptation by Naka and Kishida suggest that the photochemical reaction in the rhabdomere produces a signal proportional to the logarithm of the light intensity. Reichardt contributes a paper on the detection of quanta by the compound eye of the fly *Musca* and concludes that the receptors behave as one-quantum receptors, that is, spatial and temporal summation do not occur.

Trujillo-Cenóz and Melamed add new details (in dipterans) about the fine structure of the ommatidia and of their projection on the intermediate retina or lamina. Nunnemacher surveys the fine structure of the optic tracts of seven decapod crustacea. De Voe presents a non-linear model of sensory adaptation in the non-compound eye of the Wolf spider while Ratliff, Hartline and Lange provide two very valuable papers on the dynamics of lateral inhibition in *Limulus*. Other aspects of inhibition and excitation in this animal are given in papers by Purple and Dodge and by Adolph. Leutscher-Hazelhoff and Kuiper describe an interesting phenomenon of repetitive firing in the optic lobe of the blowfly and suggest that this could help the fly to estimate distances.

The remaining papers form a supporting background to this report on vision in the compound eye. The advances made in anatomy through the application of the electron microscope, and to the quantitative description of activity in retinal and central neurons by models expressed as computer programmes are, perhaps, the most striking feature of this valuable book. H. J. A. DARTNALL

## OBITUARIES

### Dr. Gordon Malloch

ON November 8, 1966, Dr. John Gordon Malloch died at his home in the South of France, where he had lived since his retirement in 1964.

Malloch was born in Scotland and obtained his early education at Watson's College. On coming to Canada he attended the University of Alberta where he obtained his B.Sc. and M.Sc. degrees in agricultural biochemistry. He

later obtained his Ph.D. at the University of Minnesota for a study of the amylase enzymes of wheat flour. Throughout the period of his graduate work and later he was closely associated with the many problems undertaken by the Grain Research Committee of the National Research Council of Canada, to ensure that new forms of wheat, developed for rust resistance and other features, retained their qualities for such uses as bread baking, so as to maintain the high reputation of Canadian wheat in the international market.

In 1932 Malloch was appointed to the staff of the then Division of Biology and Agriculture of the National Research Council (NRC), where he organized a cereal research laboratory. At the beginning of the Second World War he assumed responsibility for co-ordinating a large section of NRC's work concerned with chemical warfare in addition to supervising a group concerned with protective clothing and related problems. Malloch was appointed as Canadian scientific representative at the British Commonwealth Scientific Office in Washington towards the end of the war and later to the London liaison office. For his work during the war, he was awarded the M.B.E.

From 1945 to 1962 Malloch was in charge of the Canadian Scientific Liaison Office in London, one of the units of the British Commonwealth Scientific Office. In this position it was his responsibility to establish contact not only with the British scientific community, but also with scientific organizations on the continent of Europe. With his broad interests, his congenial disposition and his love of travel he rapidly became a personal friend of scientific leaders in most of the capitals of Europe; he became as much a member of the European scientific community as a representative of Canada.

During his stay in London he was chairman of the working party of the British Commonwealth Scientific Committee and during many years his industry and enthusiasm contributed greatly to the success of that organization. He also represented Canada on the Executive Council of the Commonwealth Agricultural Bureaux.

Malloch always took great interest in the scientific activities of the Organization for European Economic Co-operation (O.E.E.C.) and was, for several years, chairman of its committee for applied research, undertaking pioneer work in establishing a network of co-operative research projects between the member countries. He was also a member of the task force which in 1957 made a report to NATO that resulted in the establishment of the NATO Science Committee. In 1962, when the Organization for Economic Co-operation and Development (O.E.C.D.) was established, Malloch was appointed to Paris where he took on the dual responsibility of scientific counsellor at the Canadian embassy and scientific adviser to the Canadian permanent delegation to the O.E.C.D. From 1962-64 he represented Canada on the NATO Science Committee.

Malloch was one of the first scientists to make a career of scientific liaison, and during his long period in London he did much to establish the position of the scientific attaché. His skill as a negotiator, his talents as a committee member and his understanding of international relations made him an ideal scientist to operate in the grey area where scientific relations impinge on government policy. He had an instinctive feeling for international negotiation and, in his attempts to establish co-operation in specific fields of research, showed real understanding of the different needs of the participating countries and of how research really works. Malloch was an outstanding example of the best type of science administrator whose concepts and initiatives stemmed from an earlier and unwavering love of research.

# Implications of the Oblateness of the Sun

by

IAN W. ROXBURGH

Astronomy Centre,  
University of Sussex

Recent measurements of the oblateness of the Sun have been used to determine its quadrupole moment and thus its effect on the perihelion of Mercury. It is shown that these calculations could well be incorrect and that the measured oblateness is that expected if the Sun is slowly rotating throughout, since the surface is not one of constant potential.

DICKE has measured the oblateness of the Sun and found a difference between the equatorial and polar radii of 35 km, which amounts to 5 parts in  $10^5$  of the radius of the Sun<sup>1</sup>. In principle a measurement of the oblateness can reveal the quadrupole moment of the Sun, and because a distorted Sun produces a perihelion advance of the planets<sup>2,3</sup>, the contribution to the perihelion advance of Mercury from an oblate Sun can be determined. From the measured oblateness Dicke deduced a contribution to the perihelion advance of Mercury of 4" arc/century, which implies a mean rotation period for the inside of the Sun of 1.8 days. Because Dicke's results are of great importance both in connexion with the test of the general theory of relativity and with theories of stellar rotation, it is necessary to examine in detail the deductions from a measure of the oblateness to the value of the quadrupole moment and this is done in this article.

Dicke's deductions were made by assuming that the surface of the Sun is one of constant total potential, gravitational plus rotational, that is

$$\Psi = \frac{GM}{r} + \frac{a_2}{r^3} P_2(\cos \theta) + \Omega^2 \frac{r^2 \sin^2 \theta}{2} = \text{constant}$$

Because the surface value of  $M$ ,  $R$  and  $\Omega$  are known, the oblateness then reveals the value of  $a_2$ , the quadrupole moment. Eight kilometres of the measured 35 km are due to the surface value of  $\Omega$  so that 27 km remains to be explained. Any criticism of Dicke's argument must then devolve on the assumption that the surface is one of constant potential and this is the point which I shall examine.

The equation of hydrostatic support for a uniformly rotating star can be expressed as

$$\frac{\nabla P}{\rho} = -\nabla \varphi + \Omega^2 w = -\nabla \Psi$$

from which it follows that  $P$  and  $\rho$ , and thus the temperature  $T$ , are constant on surfaces  $\Psi = \text{constant}$ ; if the surface were then a surface of constant  $T$ , then this would be one of constant  $\Psi$  and Dicke's result could hold. The radiative flux

$$F = -\frac{4ac}{3} \frac{T^3}{\kappa \rho} \nabla T = -\frac{4ac}{3} \frac{T^3}{\kappa \rho} \frac{dT}{d\Psi} \nabla \Psi$$

is not constant, however, on an equipotential surface because  $\nabla \Psi$ , the effective gravity, varies between pole and equator and therefore the flux varies between pole and equator. With the usual definition of the surface as that point where  $T = T_e$ , with  $T_e$ , the effective temperature, given by

$$F = \sigma T_e^4$$

then we readily see that the surface  $T = T_e$  cannot be an equipotential, because  $T$  is constant over such a surface whereas  $T_e$  varies. In fact, because  $T_e$  is lower at the equator than the pole we have to go out further in the equatorial direction than the polar direction to get to the point where  $T = T_e$ . Because in the surface layers of a star we have approximately

$$T^4 = \frac{3}{4} T_e^4 \left( \tau + \frac{2}{3} \right) \tau = \int_{\tau}^{\infty} \kappa \rho dr$$

with  $\tau$ , the optical depth,  $= 2/3$  at the surface, then we have to go an extra distance

$$\Delta r = \frac{\Delta \tau}{\kappa \rho} = \frac{16}{3} \frac{\Delta T}{T} \frac{1}{\kappa \rho}$$

In the surface layers of the Sun  $\kappa \rho \sim 10^{-7}$ , and  $T_e^4$  is proportional to effective gravity, and because the effective

gravity for a uniformly rotating Sun would only vary by  $5 \times 10^{-5}$  of itself over the surface, the temperature difference would only be of the order of  $0.07^\circ \text{K}$ , corresponding to a distance of 600 cm—which is entirely negligible compared with the observed value of 35 km.

If, however, the oblateness were to result from a rapidly rotating interior, as Dicke assumes, the variation of gravity over an equipotential in the rapidly rotating core would be of order  $10^{-2}$  of itself, giving a flux variation of the same value. If flux were conserved along the equator and pole this would give a difference in effective temperature of  $15^\circ$  between pole and equator—Dicke did not observe such a difference.

This argument shows how Dicke's conclusions could be invalidated. If the surface were not one of total potential, then the surfaces of constant temperature and pressure would not coincide, and there could then be a temperature difference along an equipotential surface even though the energy flux is the same at the equator and the pole. If the temperature difference were  $\Delta T$ , then to produce a  $\Delta r$  of 30 km we would need a  $\Delta T \sim 300^\circ \text{K}$ . This would not be observable because the flux and therefore the effective temperature would be the same at equator and pole. The potential surface going through the pole would lie a distance  $\Delta r$  inside the star in the equatorial regions, and going a distance  $\Delta r$  from this potential surface at the equator would take one to the place where  $T$  had dropped to  $T_e$ .

The temperature difference  $\Delta T$  would produce a corresponding pressure difference  $\Delta P$  along a potential surface and thus a pressure force  $\Delta P/R\rho$ . In a direction normal to the equipotential the pressure force  $P/\rho l$ , where  $l$  is the scale height, is largely balanced by gravity  $g$ , and so the force along the surface can be expressed as

$$\frac{\Delta P}{R\rho} = \frac{l}{R} \frac{\Delta P}{P} \frac{P}{\rho l}$$

This pressure force would drive motions until in a steady state it is balanced by the inertial, Coriolis and viscous forces. Because inertial and viscous forces will be negligible, equilibrium is achieved when the Coriolis force balances the driving force

$$2 v_\phi \Omega \sim \frac{\Delta P}{R\rho} \sim \frac{l}{R} \frac{\Delta P}{P} g$$

$v_\phi$  is here the azimuthal component of the velocity field and corresponds to a differential rotation. Replacing  $v_\phi$  by  $\Delta \Omega R$ , where  $\Delta \Omega$  is the difference in angular velocity arising from the differential rotation, we have

$$\frac{d\Omega}{dr} = \frac{\Delta \Omega}{l} = \frac{1}{2} \frac{\Delta P}{P} \frac{g}{\Omega R^2}$$

Now the equation of hydrostatic support in the photosphere is

$$\frac{dP}{d\tau} = \frac{g}{\kappa}, \text{ that is, } P = \frac{g}{\kappa} \tau$$

thus

$$\frac{\Delta P}{P} = \frac{\Delta \tau}{2/3} \sim \frac{1}{2}$$

because  $\Delta \tau \sim 1/3$  to give a distance of 30 km. Therefore

$$\frac{d\Omega}{dr} \sim \frac{1}{2} \times \frac{1}{2} \times 2 \times 10^{-12} = 5 \times 10^{-13} \text{ rad/sec.}$$

Because the equator extends some 30 km farther than the pole, it will have a different angular velocity because there is a greater distance over which  $\Omega$  can vary. The differential rotation will then be such that

$$\frac{\Delta\Omega}{\Omega} = \frac{d\Omega}{dr} \frac{\Delta r}{\Omega} \sim \frac{1}{2}$$

that is, there will be a differential rotation of the order of 50 per cent on the visible surface. The agreement between this value and the observed equatorial acceleration  $\sim 20$  per cent supports the hypothesis that the oblateness is caused by a temperature difference, and resulting pressure difference, over equipotential surfaces.

Moreover, since the pressure gradient along an equipotential surface is positive,  $P$  increases from pole to equator; the Coriolis force must be directed outwards from the rotation axis, hence  $V\phi$  must be positive and so  $\Omega$  increases outwards, giving an equatorial acceleration. Again, more detailed models of the solar photosphere<sup>10</sup> give a change in optical depth of  $3/8$  for a distance of 30 km, and a  $\Delta T \sim 345^\circ \text{K}$  and  $\Delta P/P \sim 0.1$ . The resulting decrease by a factor 5 from our simple estimate decreases  $d\Omega/dr$  by the same factor and consequently gives an equatorial acceleration of 10 per cent, in better agreement with the observed value.

We have still left unanswered the origin of this temperature difference, and the most likely cause is the greater temperature gradient needed to transport the same amount of energy along the pole of the Sun as along the equator, the difference being caused by the stabilizing effect of rotation.

The effect of rotation on the temperature gradient in a turbulent convective medium is very difficult to estimate. Investigations on the onset of convection show that rotation tends to stabilize when the angular velocity  $\Omega$  and gravity  $g$  are in the same direction, but that the rotation perpendicular to  $g$  has no effect<sup>4</sup>. The critical Rayleigh number  $R_c$  at which convection sets in is found to depend on the Taylor number  $\tau$  through a relation of the approximate form

$$R_c = 657 + 8\tau^{2/3}$$

$$R_c = \frac{g}{T} \frac{\beta d^4}{\kappa \nu}, \quad \tau = \frac{4\Omega^2 \cos^2 \theta}{\nu^2} d^4$$

where  $\kappa$  is the thermometric conductivity and  $\nu$  the kinematic viscosity,  $d$  is the depth of the layer,  $\theta$  the angle between  $\Omega$  and  $g$ , and  $\beta$  is the superadiabatic temperature gradient. These results are of no direct use, since in the Sun turbulence is fully developed and  $\beta$  is determined by the condition that the energy flux is carried by the turbulence rather than that convection just sets in.

An estimate of the effect of rotation on turbulent energy transport has been made by Weiss<sup>6</sup> using a cellular model of convection. He found that in order to carry a flux  $F$  in the presence of rotation parallel to gravity, the superadiabatic gradient  $\beta$  had to satisfy the relation

$$\beta = \left[ \frac{8 \Omega F T}{C_p \rho g d^2} \right]^{1/2}$$

whereas when rotation is absent, or we have angular velocity perpendicular to gravity as along the equator, then

$$\beta = \left[ \frac{8 F^2}{C_p^3 \rho^2 d^3} \right]^{1/3}$$

If one inserts typical values for the solar convective zone, one finds that  $\Delta\beta$ , the difference between the superadiabatic gradient along the pole and equator, to be  $4 \times 10^{-8} ^\circ \text{K/cm}$ .

An alternative way of estimating the difference in superadiabatic gradients is to extend an idea suggested by Unno<sup>8</sup> that the largest eddies in the turbulent region are given by the linear theory for the onset of convection, but with the conductivity and viscosity replaced by the eddy conductivity and viscosity of the turbulence, that is, the turbulence so adjusts itself that under its own influence the largest modes are just unstable. This idea, which in the absence of rotation Unno showed to reduce to both the ordinary mixing length theory under certain assumptions, and also to reproduce the analysis of Ledoux,

Schwarzschild and Spiegel<sup>7</sup> under their assumptions, gives an easy way of determining the effect of rotation on the superadiabatic gradient. The results for the onset of instability can be taken over to developed turbulence by just replacing the conductivity and viscosity by their eddy equivalents in both the Rayleigh and Taylor numbers<sup>8</sup>. Since for turbulence the eddy Prandtl number  $P=1$ , and as the turbulence has to carry the flux  $F$ , we have the relation

$$\kappa = \nu = F / (C_p \rho \beta)$$

For typical values for the solar convective zone the eddy viscosity is about  $10^{13}$ , and the corresponding Taylor number about 160. The difference between the superadiabatic gradients along the equator and pole then turns out to be  $3 \cdot 10^{-8} ^\circ \text{K/cm}$ , in satisfactory agreement with the values from Weiss's theory<sup>6</sup>.

Since the solar convective zone has a depth of  $10^{10} \text{ cm}$ , it follows that on travelling this distance up the pole the equator there will be a temperature difference of

$$\Delta T = \Delta\beta \times 10^{10} = 300^\circ \text{K}$$

the value needed to explain the difference of 30 km between the radius of the equator and pole.

An alternative way of expressing these results is to ask what distance one has to travel for the temperature to drop from its value at the base of the convective zone of  $10^6 ^\circ \text{K}$  to its surface value of  $6,000 ^\circ \text{K}$ , when the temperature gradient is steeper up the pole than along the equator by an amount of order  $3 \cdot 10^{-8} ^\circ \text{K}$ , given that the actual temperature gradient is of order  $10^{-4}$  since the temperature drops by  $10^6 ^\circ \text{K}$  in  $10^{10} \text{ cm}$ . This is just 30 km. Thus the greater superadiabatic gradient needed to transport the same flux up the pole as along the equator could well be sufficient to account for the difference in polar and equatorial radii measured by Dicke.

The combination of the arguments given above would seem to support the conclusion that the pressure and temperature are not constant over equipotential surfaces near the surface of the Sun. There is a temperature difference of the order of  $300^\circ \text{K}$  over such a surface and this necessitates a larger equatorial radius than polar radius for the temperature to drop to the same surface value. The resulting pressure difference drives circulation such that in a steady state the Coriolis force on an azimuthal velocity balances the excess pressure force and this produces the equatorial acceleration. The temperature difference is caused by the different superadiabatic temperature gradients required to transport the same flux along the poles and equator of a rotating star. If the above views are substantially correct, then this implies that the surface is not a surface of constant potential so that Dicke's value for the quadrupole moment and resulting effect on the perihelion of Mercury would be incorrect. The Sun would be slowly rotating throughout, producing no detectable effect on the motion of Mercury. On the other hand, it should be admitted that our knowledge of turbulent convection in the presence of rotation is very slight, so the effects discussed here could well be incorrect. However, the fact that the assumption of a temperature difference to explain the shape also gives the equatorial acceleration must lend some support to the views expressed in this article.

# Random Close Packing and the Heats of Fusion of Simple Liquids

by

J. L. FINNEY

J. D. BERNAL

Department of Crystallography,  
Birkbeck College,  
Malet Street, London, W.C.1

Heats of fusion of inert gases can be calculated using a random close packed model of the liquid and intermolecular potential functions of the Lennard-Jones 6-12 type. Experimental agreement is improved by allowing small decreases in the nearest neighbour distances on melting. This might be expected from the fall in co-ordination, and there is experimental evidence to support it.

THEORIES of the liquid state have usually failed to predict accurately the internal energy at the melting point, and thus also the heat or entropy of fusion. This high density region is the region where simplifying approximations are least valid, although agreement with experiment may be good at low densities. Quasi-crystalline models such as that of Lennard-Jones and Devonshire<sup>1</sup> fit the solid, but fail to reproduce the internal energy in the liquid state, which suggests that such theories are rather descriptions of the solid state. Attempts to construct radial distribution functions mathematically require simplifying assumptions before a solution can be extracted. For example, the Kirkwood superposition approximation<sup>2</sup>, though satisfactory in the low density region, fails seriously for middle and high densities. The Percus-Yevick equation<sup>3</sup> is considerably better throughout, but it also fails to give accurate results at the melting point. Monte Carlo calculations<sup>4</sup> on computers seem to be the most promising approach, giving a better experimental agreement around the melting point and even suggesting the phase transition. There are, however, problems of very slow convergence at high densities, in addition to the reduction in entropy caused by using a periodic repeat cell.

In contrast, a structural approach by way of a random close packed model of the liquid state<sup>5</sup> is easy to handle in the high density region. An attempt has been made to evaluate the heats of fusion of simple liquids from this starting point with interesting and encouraging results.

The heats of fusion of the inert gases at their triple points were calculated assuming a random close packed model of the liquid state. Using a Lennard-Jones (L-J) potential function of the form

$$\phi(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad (1)$$

(Fig. 1) and the random close packing data for 1,005 centres of Scott<sup>6</sup>, the "site-energies" of the twenty-five centres nearest the centre of the mass were calculated. It can be statistically demonstrated that these twenty-five energies form part of the same distribution with a 10 per cent probability. If more centres are chosen, this becomes less plausible; the site energy begins to fall off as the sample boundary approaches the centre. Thus the chosen centres can be taken to be reasonably representative of the whole mass.

A similar calculation of site energy was made for a static face centred cubic lattice.

Because of the truncation of the potential function by the boundary in both the liquid and solid cases (though the latter can be overcome by extending the lattice) a suitable correction should be made. If the density of centres at a distance  $r_0$  and beyond is assumed to be approximately constant, then for a truncation at  $r_0$  from the centre, we apply a correction

$$\Delta E = 4\pi\rho \int_{r_0}^{\infty} r^2 \phi(r) dr$$

where  $\rho$  is the average density of sites. In the liquid  $r_0$  was taken at 4.9 diameters, at which distance the oscillations in the radial distribution function had essentially ceased. For the solid case, a sphere radius  $4.5\sqrt{2}$  diameters was used for the energy calculation;  $r_0$  was also taken at this value.

To facilitate the use of different experimentally determined Lennard-Jones parameters, curves were plotted of  $\frac{\phi(r)}{4\epsilon} : \frac{\sigma}{d}$ , where  $d$  is the distance of closest approach of two atoms in a static model, and  $\frac{\phi(r)}{4\epsilon}$  is the total potential energy of a mole in units of  $4\epsilon$  using a Lennard-Jones potential function. Two curves—one for the liquid and one for the solid—sufficed for all calculations of the heats of fusion of the inert gases considered.

Neglecting any effects resulting from vacancies in either state—these are so small that they can be treated as second order corrections to be applied later—and assuming

$$d_{\text{solid}} = d_{\text{liquid}}$$

we can evaluate the heat of fusion. For

$$\Delta U = -p\Delta V + T\Delta S \quad (2)$$

where  $\Delta U$  is the internal energy change of, say, 1 mole on changing state. Now  $p\Delta V$  can be treated as a further

Fig. 1. A Lennard-Jones 6-12 potential function of the form of equation (1), showing the significance of the parameters  $\sigma$  and  $\epsilon$ .

Table 1. INERT GAS LENNARD-JONES PARAMETERS

	$\sigma$ (Å)	$\epsilon/k$ (°K)	Ref. letter in text	Source ref.
Neon	2.749	35.60	A	10

	$4.070 \pm 0.012$	$225.3 \pm 1.1$	V	16

second order correction at the relevant pressures (all less than 1 atmosphere). Thus the heat of fusion

$$\Delta Q = \Delta U$$

For argon, using the Lennard-Jones parameters (E) (see Table 1), the calculated  $\Delta Q$  value rose from  $(1.097 \pm 0.026)$  kJ mole<sup>-1</sup> for  $d = 3.75$  Å to  $(1.284 \pm 0.030)$  kJ mole<sup>-1</sup> for  $d = 3.94$  Å giving the experimental value of  $1.176$  kJ mole<sup>-1</sup> (ref. 7) at  $d = 3.80$  Å. Now the experimental value of  $d$  is  $3.87$  Å (refs. 8 and 9), at which value  $\Delta Q = (1.251 \pm 0.029)$  kJ mole<sup>-1</sup>. This is 6 per cent too high, a discrepancy not accounted for by the expected error. The implication is a change in the distance of approach of two nearest neighbours, that is, in  $d$ . Such a fall might indeed be expected, as the co-ordination falls on melting.

This postulated change in  $d$  was calculated by taking a value of  $\Delta U$  corresponding to the experimental  $\Delta Q$  value, and reading off from the graph the value of  $d_{\text{liquid}}$  corresponding to a given  $d_{\text{solid}}$ . The error limits on the liquid curve facilitated an estimation of the error in  $d_1$ . The graphical work necessary is shown in Fig. 2.

Fig. 2. Schematic representation of the graphical work. Using a chosen L-J parameter  $\sigma$ , and  $d$  value for the solid,  $\Phi_s$ —the energy of a given mass of solid—is read off. Knowing the heat of fusion, we calculate the expected value of  $\Phi_l$  for the same mass of liquid. Hence  $\sigma/d_l$  can be read off from the liquid curve. The error limits on the liquid curve arise from variations in energy of the twenty-five chosen centres and provide an estimate of the possible error in  $d_1$ .

The results of the calculations, using the Lennard-Jones parameters tabulated in Table 1, are set out in Table 2. Postulated  $d_1$  values have been corrected for neglecting the  $p\Delta V$  term in equation (2) and also for the presence of holes in thermodynamic equilibrium in both the liquid and solid states. These corrections together amount to less than  $0.001$  Å, and are really insignificant at this level of accuracy. In some cases, experimental data conflict. Where a value of  $d$  is obtained indirectly, the way in which it is reached is indicated at the foot of the table.

**Neon.** The predicted  $d_1$  value is slightly larger than suggested by experiment, though the order of magnitude is the same. The two extreme sets of Lennard-Jones parameters give a variation in  $d_1$  over  $0.01$  Å. Averaging over the set for  $d_s = 3.20$  Å, we obtain

$$d_1 = (3.18_s \pm 0.00_s) \text{ Å}$$

compared with the experimental  $3.17$  Å.

**Argon.** The second and third sets of data give the best agreement with experiment. The first set of values for  $d_s$  appears, however, to be more reliable, and here the predicted  $d_1$  is slightly lower than found experimentally. Averaging over the five different sets of Lennard-Jones parameters

$$d_1 = (3.84_s \pm 0.01_s) \text{ Å}$$

compared with the experimental  $3.86$  Å. It is worth noting as a general point that parameter sets H and J are given with a quoted error, which inflates the estimated error in  $d_1$ : this would imply all other quoted errors are underestimated.

**Krypton and xenon.** With the heavier noble gases, we are working very close indeed to the bottom of the potential well in  $\phi(r)$  and thus we would expect the calculations to be more sensitive to changes in Lennard-Jones parameters. Moreover, as reference to Table 1 shows, different workers have obtained very different values for these

Table 2 (a). SUMMARY OF NEON DATA

$$\Delta Q = 0.335 \pm 0.002 \text{ kJ mole}^{-1} \text{ (ref. 7)}$$

$$T_f = 24.55^\circ \text{ K (ref. 7)}$$

$$P_f = 325 \text{ mm (ref. 21)}$$

$$\text{Atomic weight} = 20.183$$

$d_s$ (expt.) (Å)	Ref.	L-J ref.	$d_1$ (theory) (Å)	$d_1$ (expt.) (Å)	Ref.	Notes
3.207	9	A	$3.18_s \pm 0.00_s$	3.17	22	(1)
		B	$3.18_s \pm 0.00_s$			
		C	$3.19_s \pm 0.00_s$			
		D	$3.18_s \pm 0.00_s$			
3.202	7	A	$3.17_s \pm 0.00_s$	3.17	22	(2)
		B	$3.18_s \pm 0.00_s$			
		C	$3.18_s \pm 0.00_s$			
		D	$3.17_s \pm 0.00_s$			

Notes: (1)  $d_s$  calculated from density. (2)  $d_s$  calculated from density using the earlier value of volume change on melting.

If we extrapolate the value of  $d_s$  at  $4.2^\circ \text{ K}$  quoted in ref. 22 assuming an expansion similar to solid argon, we find  $d_s \sim 3.21$  Å, which gives support to the values taken.

Table 2 (b). SUMMARY OF ARGON DATA

$$\Delta Q = 1.176 \pm 0.001 \text{ kJ mole}^{-1} \text{ (ref. 7) (see note (1))}$$

$$T_f = 83.78^\circ \text{ K (ref. 9)}$$

$$P_f = 516 \text{ mm (ref. 7)}$$

$$\text{Atomic weight} = 39.944$$

 \* It is impossible to obtain a fit for this function.

parameters, giving a confused picture. The amount of experimental evidence on neighbour distances is also very sparse, which suggests that caution should be applied in treating the results until more independent measurements are available.

For krypton, the predicted  $d_l$  varies from 4.11<sub>6</sub> to 4.07<sub>8</sub>. This change is in the right direction, but of magnitude insufficient in the light of the experimental 4.02 Å. Error in the parameters is quoted only for set P, implying, as mentioned in the case of argon, that quoted errors in  $d_l$  are underestimated. Averaging over all six sets, for what it is worth,  $\bar{d}_l = (4.09_7 \pm 0.01_6)$  Å.

The situation with xenon is even more uncertain. One set of  $\phi(r)$  parameters makes a fit impossible, while sets S, T and V suggest an increase in  $d$  on melting. Set U predicts a small fall, though this is perhaps one of the less reliable Lennard-Jones functions. The error for set V contains an error quoted for the parameters, again suggesting an underestimate for the others. Experiment suggests a small fall, or little change in  $d$ . The average theoretical  $d_l$  is

$$(4.48_2 \pm 0.04_2) \text{ Å}$$

compared with the experimental value of about 4.43 Å.

In both these cases, the sensitivity to the potential function and the limited amount of experimental data leave an inconclusive picture.

Uncertainty in the density of the random model thwarts any attempt to calculate the volume change on melting, taking the change in  $d$  into account. In order to obtain accurately the average packing density and local density fluctuations, the concept of the Voronoi polyhedron was used<sup>32</sup>. If we draw planes perpendicularly bisecting imaginary straight lines between a centre and its neighbours, and take the smallest closed polyhedron thus obtained (ensuring no part of the polyhedron can be intersected by continuing this process with more distant centres), we will have selected a volume in which all points within the polyhedron are closer to the central point than to any other. This polyhedron is the Voronoi polyhedron associated with the central point: for simplicity, the construction of its two dimensional counterpart is shown in Fig. 3. The average density of the first

four hundred centres thus calculated is 63.48 per cent, while that of the central region—of greater relevance to these "liquid site energy" calculations—is 64.32 per cent. There is still great uncertainty about the maximum density of random packing, a limit which some of our recent work suggests to be statistical rather than absolute; for the densities of the polyhedra are distributed throughout the range from 57 per cent to 70 per cent, with no obvious peak or structural significance attached to the overall average. In such circumstances, a really accurate calculation of  $\frac{\Delta V}{V}$  is not possible. A larger sample may

well improve the situation, when an extension to systems with different density changes on melting—including those which contract—may show interesting results.

The transition from hard spheres to a more realistic potential function attempted here is admittedly rather crude.  $d$  has been taken as the closest approach distance; in fact, this should be modified to take account of thermal fluctuations which would allow molecules to approach closer than this. The kinetic energy leading to such close approaches would, however, be the same in the solid as the liquid, though it might be argued that the generally stronger repulsive fields in the solid resulting from a higher packing density would give a higher proportion of "squashed" molecules in the liquid. This would lead to a slight lowering of the "liquid site energy", giving a greater fall in  $d$  on changing state—required for neon, krypton and xenon, but not argon. In connexion with this, it is worth noting that errors in measuring a hard sphere array do give some centres closer together than  $d$ , thus allowing for a small amount of squashing. Working along these lines it may even be possible to adjust the error function to represent that part of the potential function for which  $r < d$ .

With more data on random packing at different densities, and a simulation of thermal motions in both the liquid and solid states, it may be possible to investigate more fully some of these factors, and to fit accurately the density changes. Without more and accurate data on experimental approach distances and interatomic potential functions, however, this would scarcely at present seem justified.

Probably the most doubtful assumption made here is that of taking the twenty-five chosen liquid centres as a reasonable sampling of the random model. The variation

Fig. 3. Construction of a Voronoi polygon.

in "site energy" is perhaps sufficiently large ( $\sim \pm 5$  per cent) to invalidate the concept of an "average" in such a homogeneously irregular array. To allow for this, we could either estimate the reduction in entropy expected from repeating such arrays (which requires assuming no repeating in the real case, which may be a doubtful premise), or use a series of progressively larger samples to see how the entropy of mixing of such samples would change with size. The large variations in the local density of the model suggest the need for a much larger sample to increase the reliability of these calculations: we shall measure such a model ( $\sim 3,000$  centres) in the near future.

In view of the connexion between the change in nearest neighbour distance on fusion and (a) the radial distribution function, and (b) the co-ordination number, this approach by way of the heat of fusion may be a duplicative path. It is, however, more straightforward, less ambiguous and, we suspect, considerably more sensitive to the structural arrangement. We have not attempted to consider the possibility of non-uniqueness of a given "site-energy" with respect to different arrangements: what has been attempted here merely shows how a random model of the liquid state may fit. Moreover, the fact that realistic results can be obtained from an initially apparently unrealistic hard sphere array is very encouraging and worth emphasizing. An extension of the argument to simple metals will provide a more rigorous experimental comparison. In principle we could extend it even further to polyatomic molecules, with directed bonds, though lack of precision in our knowledge of the forces involved would probably make it quantitatively impossible to handle in practice.

## Aliphatic Hydrocarbons in Pre-Cambrian Rocks

by

J. ORÓ  
D. W. NOONER

Department of Chemistry,  
University of Houston,  
Houston, Texas

Analyses of sedimentary rocks from the Pre-Cambrian of South Africa show that they contain a variety of alkanes. Were these hydrocarbons incorporated into the sediments at the time of sedimentary deposition, and are they biogenic in origin?

ALKANES of high molecular weight have been found in shale  $1 \times 10^9$  yr old from the Nonesuch formation<sup>1,2</sup>, chert  $2 \times 10^9$  yr old from the Gunflint iron formation of Ontario, Canada<sup>3</sup>, and rocks (carbonaceous lenses and graphitic silicates)  $2.7 \times 10^9$  yr old from the Soudan iron formation of Minnesota<sup>4-6</sup>. These alkanes include the saturated isoprenoid hydrocarbons, pristane and phytane. The biogenic origin of the organic materials in the Nonesuch shale and the Gunflint chert has been assigned on the basis of fossil micro-organisms contained in them<sup>7</sup> and the hydrocarbons were considered to be remnants of this early life.

We have analysed sedimentary rocks  $3.2 \times 10^9$  yr old from the Fig Tree series of the Swaziland system, eastern Transvaal, South Africa, for aliphatic hydrocarbons, using techniques described in detail elsewhere<sup>8,9</sup>. The carbonaceous silicate rocks from the Fig Tree series were collected by T. C. Hoering in the Sheba gold mine near Barberton, South Africa, and by E. S. Barghoorn in an outcrop near the Daylight mine, 28 km E.N.E. of Barberton. The rocks were black chert (sample No. 1) and a carbonaceous graphitic silicate (sample No. 2) collected by Hoering, and black chert (sample No. 3) collected by

Barghoorn. In addition, an extract obtained at the Geophysical Laboratory of the Carnegie Institute of Washington by Hoering from a core specimen of shale (sample No. 4) was analysed.

The procedure used with samples 1, 2 and 3 was to pulverize the rocks (after surface contaminants had been removed) in a Carver press test cylinder, and extract the organic compounds with benzene-methanol (3:1) in a glass 'Soxhlet'-type extractor. The extract supplied by Hoering was obtained from sample No. 4 by extracting 300-400 g of the crushed shale (core sample) in an ultrasonic generator with *n*-pentane. The solvent extracts were then fractionated on silica gel. The procedure of Meinschein and Kenny<sup>9</sup> was followed except that the aliphatic hydrocarbons were eluted with *n*-pentane in the case of sample No. 4. By carefully blowing the low boiling solvent (*n*-pentane) to a very small volume, many of the relatively low molecular weight hydrocarbons, ordinarily lost by evaporation to dryness when *n*-heptane is used, were recovered.

The eluates were dissolved in benzene and suitable aliquots taken for analysis by gas chromatography and combined gas chromatography-mass spectrometry<sup>10</sup>. For

the gas chromatographic analyses tentative identification of the separated compounds was obtained by (1) coinjection of pristane, phytane, *n*-octadecane, and *n*-octadecene-1 with the samples (samples 1 and 4) on capillaries coated with 'Polysev' (*m*-bis-*m*-(phenoxyphenoxy)-phenoxybenzene); and (2) comparison of the retention times of the compounds in the samples (samples 1-4) with those of appropriate hydrocarbon standards (normal alkanes, pristane, phytane, *n*-hexadecene-1, *n*-octadecene-1, *n*-eicosene-1, and *n*-tricosene-1) chromatographed on the same columns ('Polysev') and under the same conditions. For the graphitic-like silicate (sample No. 2), in addition to the comparison of retention times of eluted components and standards (normal hydrocarbons, pristane and phytane) made with 'Polysev' as the liquid phase, similar comparisons were made using a 15 m packed column with 'SE-30' as the liquid phase.

Mass spectrometric identifications (samples 1 and 4) were made by taking individual mass spectra of the individual components as they were eluted from the 'Polysev' coated capillary<sup>11</sup>. These spectra were compared with spectra of the standards, which were treated in the same manner. Because we did not have a standard, the assignment of norpristane was made by comparing our mass spectrum with available C<sub>18</sub> isoprenoid mass spectra<sup>2</sup>.

Fig. 1 shows the chromatograms obtained using 'Polysev' as the liquid phase in stainless steel capillary columns. The hydrocarbons shown in Fig. 1A were obtained from the internal part of a chert sample (sample No. 1), which was treated with chromic acid cleaning solution before crushing and extracting. Normal alkanes ranging from C<sub>16</sub> through C<sub>26</sub> were found to be present. The peaks designated as *a* and *b* correspond by their chromatographic position to pristane and phytane, respectively. The peak immediately following *n*-C<sub>18</sub> contains Δ-C<sub>18</sub>, but probably also contains norpristane. The shape of the peak clearly shows that it represents at least two compounds. The peaks immediately following *n*-C<sub>18</sub>, *n*-C<sub>20</sub> and *n*-C<sub>22</sub> correspond to the normal C<sub>18</sub>, C<sub>20</sub> and C<sub>22</sub> monoenes, respectively. The retention times do not correspond to the respective *n*-alkylcyclohexanes. The retention times of these cyclic alkanes (on 'Polysev') almost coincide with those of normal alkanes having one more carbon. As indicated, the identification of the olefines was made on the basis of both mass spectrometric analysis and retention times of known hydrocarbons (normal C<sub>16</sub>, C<sub>18</sub>, C<sub>20</sub> and C<sub>22</sub> monoenes). The gas chromatographic analysis of this sample made on the LKB '9000' instrument is shown in Fig. 1E.

A second analytical determination of alkanes was carried out with small pieces (inside and outside) of the same specimen of chert. The decontamination of possible surface contaminants was performed this time not by treating with chromic acid, but by carefully extracting the rock surface with organic solvent (benzene-methanol, 3:1). After extraction the pieces were then dried, crushed, extracted and the extract analysed.

The chromatographic pattern of the paraffinic hydrocarbons recovered from the sample is shown in Fig. 1C. As shown, the chromatographic pattern is the same as that of Fig. 1A. Approximately the same level of hydrocarbons (0.02 p.p.m.) was found in sample No. 1 by the two separate and slightly different analytical determinations. The mass spectrometric results of the second determination were essentially as obtained for the first. Furthermore, in the second analysis, two mass spectra were taken of the peak immediately following *n*-C<sub>16</sub>, one on the ascending side of the peak before inflexion and the other on the descending side. The components of this peak were found, in fact, to be norpristane and C<sub>16</sub> monoene as indicated by the first analysis. The mass spectra of the isoprenoid hydrocarbons of this sample are presented in Fig. 2. They are essentially identical to those given by standards. The controls or procedural

blanks (glass was carried through all analytical steps including pulverization in the Carver press associated with the particular samples) are shown in Fig. 1B and 1D. As seen, the alkane contribution of the blanks amounts to less than 1 per cent and 5 per cent, respectively, of the amounts found in the actual samples.

Sample No. 2 (graphitic-like silicate obtained from Hoering) and sample No. 3 (black chert obtained from Barghoorn) were boiled in benzene-methanol (3:1) to remove any possible surface contamination. The *n*-heptane eluates from these samples were analysed on a 305 m long × 0.76 mm inside diameter stainless steel capillary coated with 'Polysev'. Extremely low levels of hydrocarbons (approximately 0.003 p.p.m.) were obtained. Small peaks representing hydrocarbons in the C<sub>12</sub>-C<sub>18</sub> range were obtained. Peaks having the retention time of pristane and phytane standards were detected in the graphitic-like silicate, but not in the chert. The much lower yields obtained with these two samples show that significant variations in the hydrocarbon content of these rocks exist. In general, variations in hydrocarbon content can be expected from different samples of the same sediment. Significant variations have been observed in our laboratory in rocks from the Gunflint iron formation of southern Ontario. The existence of such rocks deficient in hydrocarbons makes it possible to run ideal analytical controls for samples from the same formation which may be richer in hydrocarbons. The heterogeneity of quanti-

Fig. 1. Gas chromatographic separation of alkanes from the Fig Tree chert with capillary columns ('Polysev'). A, Stainless steel tubing 91.5 m × 0.076 mm, coated with 'Polysev'. F and M model 810 gas chromatograph was equipped with a flame ionization detector. Nitrogen pressure, 1.050 g/cm<sup>2</sup>. No split. Chert extracted (pulverized inside piece), 100.5 g. About half of the *n*-heptane eluate was injected. Range 10; attenuation, 4. Isothermal at 140°C for 22 min, then raised to 200°C at approximately 6°C/min. B, Blank (pulverized glass was substituted for the sample), treated in the same way as the sample. C, Analytical equipment and conditions are the same as for A. Chert extracted (pulverized piece which included some outside material cleaned with solvent), 97.9 g. About half of the *n*-heptane eluate was injected. D, Blank (pulverized glass substituted for sample), treated as sample. E, Stainless steel tubing, 75 m × 0.76 mm, coated with 'Polysev'. LKB '9000' gas chromatograph-mass spectrometer combination. Helium flow, 24 ml./min. No split. Same sample and eluate as in A. About a third of the eluate was injected. Gain, 6. Isothermal at 130°C for 18 min, then raised to 200°C at about 1.5°C/min.

tative distribution of hydrocarbons may be the result of differences in the concentration or composition of organic matter or in the thermal metamorphism of the rocks analysed. This heterogeneity may be taken as an indication that the hydrocarbons were not incorporated into the rocks by a general process of petroleum migration in more recent times.

In order to obtain additional data on Fig Tree Pre-Cambrian sediments, a core of the Fig Tree shale (sample No. 4) was extracted (see previously) more recently at the Geophysical Laboratory of the Carnegie Institute of Washington by Dr. T. C. Hoering, and the resulting hydrocarbons were analysed at Houston. The results obtained were similar to those of Fig. 1 except that more of the low molecular weight alkanes and less of the higher molecular weight paraffins were detected. This is indeed what would be expected by the use of *n*-pentane as a solvent instead of *n*-heptane. The amounts of hydrocarbons were of the order of 0.15 p.p.m.

Aliphatic hydrocarbons are present in the Fig Tree rocks at extremely low levels (0.003–0.15 p.p.m.). Sufficient data are not available to ascertain whether or not the hydrocarbons date from deposition. The treatment of the samples, however, precludes the hydrocarbons being merely surface contaminants. This conclusion is in line with the fact that the  $^{13}\text{C}/^{12}\text{C}$  ratios of the extractable and insoluble organic matter of the Fig Tree rocks are essentially identical<sup>12</sup>. Hoering's comments<sup>12</sup> on the discrepancies for this correlation that occur for several Pre-Cambrian samples, however, indicate that more work on carbon isotope distribution needs to be done before the actual significance of  $^{13}\text{C}/^{12}\text{C}$  ratios can be ascertained. Entities have been found in the Fig Tree shale that have the morphology of fossil bacteria and possibly of algae<sup>13</sup>, and these hydrocarbons may be remains from this early life.

The occurrence of olefines in some samples of Fig Tree chert is somewhat unexpected. Although olefines have been observed in Pennsylvania crude<sup>14</sup>, in general they

are relatively rare in petroleum crudes and sediments. Their presence in the cherty Pre-Cambrian sediment is not easily understood unless one assumes that the olefines can be preserved in the chert matrix for long periods of time or that they may be products of the thermal degradation of biological compounds such as even carbon-numbered alcohols.

The relatively large amounts of pristane found in the sediment may be taken as an indication that the isoprenoid hydrocarbons are probably biogenic. It has been demonstrated, however, that 2-methylbutane (isoprane) and other branched hydrocarbons can be synthesized by Fischer-Tropsch processes<sup>15,16</sup>. Thus it is not impossible that certain isoprenoid hydrocarbons could also be formed abiotically. More work needs to be done on this type of synthesis before advancing any speculations.

To our knowledge no assignment of configuration to the asymmetric centres of fossil pristane and phytane has been made. With the further development of some recent techniques using optically active phases<sup>17</sup> it may eventually be possible to separate the stereoisomers (for example, enantiomers, diastereomers) of pristane and phytane. Then the aforementioned assignments of configuration would be feasible and it might be possible to differentiate between abiologically and biologically derived isoprenoids. Although we do not know the isomeric forms of the isoprenoid structures examined, we do not believe, on the basis of the gas chromatographic and mass spectrometric data, the compounds to be isomers in which methyl substituents are displaced from the positions found in pristane and phytane. Nevertheless, it is possible that our methods might not detect a shift in position of only one methyl group.

After completing this work, we have learned that isoprenoid and paraffinic hydrocarbons have also been detected by other workers in samples of the Fig Tree chert which had apparently undergone a minimum amount of thermal metamorphism (Meinschein, W. G., personal

Fig. 2. Mass spectra of saturated isoprenoid hydrocarbons from the Fig Tree chert sample extracted in Houston. Obtained using an LKB '9000' gas chromatograph-mass spectrometer combination.

communication) and in similar rocks which presumably were more metamorphosed<sup>12</sup>. The organic geochemistry of Pre-Cambrian sediments and the problems involved in assessing the role of contamination and metamorphism, and determining whether the hydrocarbons date from sediment deposition or are the result of later infiltrations into the rock, have been recently discussed in some detail by Hoering<sup>13</sup>.

Because of the compact nature of some of these rocks, especially the chert, and the fact that internal samples were analysed in most cases, it is probable that the hydrocarbons are indigenous to the rock. The fact that microfossils have been found in some of these rocks would suggest a biochemical origin for these hydrocarbons which took place about  $3.2 \times 10^9$  yr ago. Additional research will have to be carried out, however, in order to decide in a more definite way whether these hydrocarbons date from sediment deposition and whether they are biogenic or not.

We thank T. C. Hoering, E. S. Barghoorn and W. G. Meinschein for samples and valuable comments. This work was presented at the fourth meeting of the Group for the Analysis of Carbon Compounds in Carbonaceous Chondrites, Washington, April 21, 1966, and at the Third International Meeting on Organic Geochemistry, London, September 28, 1966. It was supported in part by research grants from the U.S. National Aeronautics and Space Administration.

## Aliphatic Hydrocarbons in Meteorites

by  
J. ORÓ  
D. W. NOONER  
Department of Chemistry,  
University of Houston,  
Houston, Texas

Naturally occurring mixtures of terrestrial isoprenoids and other aliphatic hydrocarbons give the same chromatographic patterns as aliphatic hydrocarbons from carbonaceous chondrites; carbonaceous chondrites Wiik Types II and III show substantially higher contents of aliphatic hydrocarbons than meteoritic graphite nodules and Type I carbonaceous chondrites. Any theory of the origin of hydrocarbons in meteorites must explain these features.

BEFORE the development of suitable analytical techniques for the analysis of trace quantities of organic compounds, a number of investigators of meteorites, including Wöhler, Meunier, Roscoe, Tschermak, Friedheim and Berthelot, reported indication of hydrocarbons in various carbonaceous meteorites<sup>1</sup>. Following Mueller<sup>2</sup>, who in 1953 examined the Cold Bokkeveld meteorite and reported the presence of extractable organic material, several investigators have found traces of organic compounds, particularly hydrocarbons, in carbonaceous and other chondrites<sup>3-9</sup>. These hydrocarbons have been regarded as being remnants of extraterrestrial life<sup>4,5</sup> or products of abiotic synthesis<sup>7,9</sup>. Terrestrial contamination has been considered a possible source for some of the organic compounds<sup>10</sup> but has largely been ruled out for the hydrocarbons<sup>4,7</sup>.

The work reported here was carried out to provide a comparative study on the qualitative and quantitative distribution of isoprenoid and other aliphatic hydrocarbons in carbonaceous chondrites

Fig. 1. Example of the gas chromatographic separation of aliphatic hydrocarbons from meteorites. Stainless steel tubing, 152.5 m long  $\times$  0.076 cm inside diameter, coated with 'Polyseal'. 'F' and 'M' Model 810 gas chromatograph equipped with a flame ionization detector. Nitrogen pressure, 1.050 g/cm<sup>2</sup>. No split. Meteorite extracted (Vigarano sample from Nagy), 0.5 g. About 1/5 of the *n*-heptane eluate was injected. Range 10°; attenuation, 2. Programmed from 122° to 175° C at approximately 2.0° C/min. a, Pristane; b, phytane.

and related meteorites and to ascertain, if possible, the origin of these hydrocarbons.

The meteorites (0.2 to 8.6 g) were pulverized to approximately 100 mesh, placed in an all-glass Soxhlet-type extractor and extracted with 50 ml. of a benzene-methanol (3:1) mixture for 8 h. After careful evaporation, the extracts were fractionated by silica gel chromatography, eluting successively with 15 ml. of each of three solvents: *n*-heptane, benzene and methanol. The residues from the *n*-heptane eluates, which usually contained less than 0.1 mg hydrocarbon, were dissolved in a few microlitres of benzene and suitable aliquots (about 1  $\mu$ l.) were taken for analyses.

The gas chromatographic analysis was carried out using long (100 to 1,000 ft.) stainless steel capillary columns coated with different stationary phases, such as 'Apiezon L', 'Polysev', 'Igepal Co-880' and 'SF-96', and other phases specifically suitable for the separation of normal and isomeric aliphatic hydrocarbons. Efficiencies of more than 300,000 theoretical plates were obtained with some of the long columns. 'Barber-Colman Series 5000' and '5320' and 'F and M Model 810' gas chromatographs with flame detectors were used for this purpose. The combined gas chromatographic-mass spectrometric analysis was carried out using 250 ft. long capillary columns, and mainly an LKB '9000' gas chromatograph-mass spectrometer. The mass spectra of the hydrocarbons were obtained at 70 eV as they emerged from the column. Other details of the analytical methods have been described previously<sup>8</sup>.

The meteorites examined belong to the following five groups: non-carbonaceous chondrites; graphite nodules from iron meteorites; and Wiik Types I, II and III carbonaceous chondrites.

The results of this study are recorded in a number of gas chromatograms and mass spectrograms and they are summarized in Table 1. As shown in Table 1, isoprenoid and other aliphatic hydrocarbons were found in varying amounts in practically all the meteorites investigated. The identification of isoprenoid hydrocarbons was carried out by combined gas chromatography-mass spectrometry for the Boriskino, Mighei, Murray, Santa Cruz, Mokoia and Odessa (graphite nodule) meteorites. The identification of these hydrocarbons in the other meteorites was carried out by gas chromatography by comparing their retention times with those of hydrocarbon standards in at least three different columns. See Fig. 1 for an example of a gas chromatographic separation on 'Polysev'.

It will be observed that the concentration of aliphatic hydrocarbons in the graphite nodules is comparable with that of Type I carbonaceous chondrites. Also, the amounts in Type II are comparable with those in Type III carbonaceous chondrites, particularly if the results from the Grosnaja meteorite are excluded. This meteorite contains a large amount of alkanes (415 p.p.m.) resembling industrial paraffin waxes. Thus taking average values, three major concentrations of hydrocarbons can be distinguished which divide meteorites into the following groups: (a) non-carbonaceous chondrites; (b) graphite nodules and Type I carbonaceous chondrites; and (c) Types II and III carbonaceous chondrites. The approximate average values for the isoprenoid and total (isoprenoid + normal) aliphatic hydrocarbons for these three levels are respectively: (a) 0.06 and 1.8 p.p.m.; (b) 0.6 and 8 p.p.m.; and (c) 9 and 60 p.p.m. Thus in going from one of these levels to the next, the isoprenoids increase approximately by a factor of 10-15 and the total (isoprenoid + normal) aliphatic hydrocarbons by a factor of 4-7.

In the case of the graphite nodules the external portions had about five times more hydrocarbons than the internal portions, indicating that the hydrocarbons were acquired from the outside or had been destroyed in the inside. Similar results were obtained with inside and outside samples of the Orgueil meteorite. Significant variations in

the qualitative and quantitative distribution of hydrocarbons for different meteorites and for different samples of the same meteorite were found. Almost all the carbonaceous chondrites which belonged to Wiik Type II, however, gave essentially the same qualitative gas chromatographic pattern although with quantitative variations. Whereas Type I carbonaceous chondrites appeared to contain very small amounts of isoprenoid hydrocarbons, Type II carbonaceous chondrites showed generally high levels. For example, in the Boriskino, Mighei and Santa Cruz meteorites, amounts as high as 20-30 per cent of the total hydrocarbon content were observed. The major isoprenoid compound found in essentially all cases was pristane. No pristane or phytane was found in the Ornans (Type III) and the amounts in the Orgueil (Type I) and in the non-carbonaceous chondrites were almost negligible.

No predominance of hydrocarbons with an odd number of carbon atoms over those with an even number was

<sup>a</sup> Isoprenoid plus normal alkanes.

† The values for Grosnaja have been excluded from the average.

The amounts of hydrocarbons given in this table are those obtained when the procedure described is followed. They do not necessarily represent all of the aliphatic hydrocarbons in the original sample because of some losses occurring during solvent removal after extraction and elution.

Meteorite samples were obtained from the following people.

(1) R. E. Folinsbee, University of Alberta. (2) C. B. Moore, Arizona State University and Ninninger Meteorite Collection. (3) G. W. Hodgson, Research Council of Alberta. (4) G. Mueller, Birkbeck College, University of London. (5) C. F. Lewis, Centre for Meteorite Studies, Arizona State University. (6) G. I. Huss, American Meteorite Laboratory. (7) B. Mason, American Museum of Natural History. (8) E. Anders, Enrico Fermi Institute for Nuclear Studies, University of Chicago. (9) A. Cavaillé, Museum of Natural History, Montauban, France. (10) B. Nagy, University of California (San Diego). (11) E. P. Henderson, Smithsonian Institution, U.S. National Museum. (12) K. Fredriksson, Smithsonian Institution, U.S. National Museum. (13) G. Kurat, Museum of Natural History, Vienna. (14) E. J. Olsen, Chicago Natural History Museum.

observed, with the exception of some samples of the Orgueil meteorite, which showed a slight odd predominance in the  $C_{15}$  and  $C_{22}$ - $C_{27}$  ranges. This may indicate a biological origin in line with optical activity measurements<sup>11</sup>. The distribution of hydrocarbons in the Ivuna, Alais and Warrenton meteorites showed two maxima which indicated two populations of hydrocarbons and implied two different sources or synthetic processes. A number of terrestrial samples including Pre-Cambrian sediments, graphites and crude petroleum were found to contain hydrocarbons giving essentially the same gas chromatographic pattern as those given by the carbonaceous chondrites.

Any theory of process or processes, terrestrial or extra-terrestrial, responsible for the presence of hydrocarbons in meteorites must explain the foregoing qualitative and quantitative variations and similarities. The data on the higher concentration of hydrocarbons in the external part of the graphite nodules and some samples of the Orgueil meteorites are best explained by terrestrial contamination. The data on the predominance of odd carbon number alkanes in some Orgueil samples suggest a biological origin. More research work will be needed, however, before one can state with certainty that the hydrocarbons in meteorites are the result of terrestrial biological contamination. Interesting alternative possibilities are a lunar-terrestrial biological origin postulated by Urey<sup>12</sup> or an abiological extraterrestrial origin obscured or modified by terrestrial (or extraterrestrial) hydrocarbons of biological origin<sup>9,13</sup>.

This work was supported in part by the U.S. National Aeronautics and Space Administration. We thank those who gave meteorite samples (see Table 1). We also thank Professors H. C. Urey, W. F. Libby and other investigators of the group for the analysis of carbon compounds in carbonaceous chondrites, for valuable help or comments.

## Action of Atomic Hydrogen on Ribonuclease in Aqueous Solution

by

BARBARA E. HOLMES

Department of Radiotherapeutics,  
University of Cambridge

GIL NAVON

GABRIEL STEIN

Department of Physical Chemistry,  
Hebrew University, Jerusalem, Israel

Atomic hydrogen seems to react with ribonuclease in aqueous solution, not by attacking the molecule at random, but by reacting with specific amino-acids in the enzyme. It seems to have a special affinity for aromatic and sulphur-containing amino-acids, even though these may be some way from the surface of the enzyme.

WE have examined the action of hydrogen atoms on dilute aqueous solutions of ribonuclease (RNase). The results now obtained correlate with those previously obtained for aqueous solutions of simple inorganic and organic compounds<sup>1</sup>, amino-acids<sup>2</sup>, the enzyme proteins chymotrypsin<sup>3</sup> and also cytochrome *c* (ref. 4), which contains a reducible metal ion; and with those recently obtained on solutions of oxidized and reduced glutathione (unpublished work).

For the quantitative study of the reactions of atomic hydrogen with solutes in water, hydrogen ions are produced<sup>1</sup> by a high frequency (30 Mc/s) electrodeless discharge in pure hydrogen at a pressure of 27 mm of mercury and swept through the solution at a pumping velocity of 50 l./min. Oxygen is, of course, excluded from the apparatus. To ensure maximum reproducibility<sup>5</sup> ( $\pm 10$  per cent) the experimental arrangements cause far-reaching recombination before the gas stream enters the solution. Thus a reproducible low concentration of hydrogen atoms, with no other reactive species present, is carried into the solution in a stream of a large excess of inert hydrogen molecules.

The dose rate of hydrogen atoms, in the present series of the order of  $3 \times 10^{-4}$  moles/l. min, was determined exactly before and after each experiment using the ferricyanide dosimeter<sup>6,7</sup>. The solutions were kept at 4° C during experiments to decrease evaporation. The low temperature also helps to decrease reaction by agents other than hydrogen atoms.

The relative rate constants, and from these absolute rate constants, can be calculated from the experimental results according to a procedure described previously<sup>1</sup>. Critical comparison with rate constants of hydrogen atom reactions obtained from radiation chemistry showed that the results agreed within a factor of 2, using a variety of different solutes, over the range  $10^5$ - $10^{10}$  l./mole sec. The present method makes it possible to study the reactions of one of the species active in radiation chemistry and photochemistry separately, in the absence of other reactive species and over a wide range of pH.

Atomic hydrogen is in theory one of the simplest reagents in aqueous solution. Its use allows the study of rates and mechanism with specific substrates without ionic effects and solvent interaction affecting the reagent.

In the present series the substrate was crystalline bovine pancreatic ribonuclease in solutions of 0.5 mg/ml., that is,  $3.7 \times 10^{-5}$  moles/l. Experiments were either at pH 6, with no other solute added, or at pH 1 adjusted by adding hydrochloric acid. The latter does not react chemically with hydrogen atoms (unpublished observations) and influences the results by its pH effect alone. At both pH values control experiments, in which the gas stream was bubbled through the solution but hydrogen atoms were not present (discharge unlit), showed that appreciable enzyme inactivation or product formation was not caused in the absence of hydrogen atoms by bubbling alone.

As in the case of trypsin<sup>8</sup>, we first investigated enzyme inactivation, changes in the absorption and fluorescence spectrum and the formation of sulphhydryl groups and free hydrogen sulphide.

To assay enzyme activity purified RNA was used. We followed the procedure of Anfinsen *et al.*<sup>9</sup>. We used Ellman's unmodified procedure<sup>10</sup>, taking  $\epsilon_{412m\mu} = 1.36 \times 10^4$  for the product with DTNB. Hydrogen sulphide was trapped in the stream of effluent hydrogen in two cooled liquid nitrogen traps arranged in series. More than 90 per cent of the product was found in the first, less than 10 per cent in the second trap. Control experiments with known amounts of hydrogen sulphide evolved in solutions showed that recovery was about 90 per cent, so that our hydrogen sulphide determinations are somewhat low. For the determination of hydrogen sulphide we followed the procedure described previously<sup>2,3,8</sup>, but redetermined  $\epsilon = 1.8 \times 10^4$  for the product with DMPD, using sodium sulphate decahydrate titrated iodometrically as the standard.

Fig. 1 shows the results on enzyme inactivation, sulphhydryl and hydrogen sulphide formation at pH 6. In Table 1 these results are compared with some obtained at pH 1. Brining the enzyme to pH 1 changes its configuration but does not inactivate it irreversibly<sup>11</sup>.

Table 1. COMPARISON OF SOME RESULTS OF TREATMENT WITH HYDROGEN ATOMS AT pH 6 AND pH 1

pH	Dose rate $10^{-5}$ moles/l.min	Total dose $10^{-5}$ moles/l.	Hydrogen sulphide formed, $10^{-5}$ moles/l.	Sulphhydryl groups formed, $10^{-5}$ moles/l.	Inactivation $10^{-3}$ moles/l. (%)
6	28	42	2.7	1.2	0.92 25
1	34	51	10.3	0.3	1.95 58

The observed rates of inactivation at both pH values are similar to but slightly lower than the corresponding values for trypsin<sup>8</sup>. Using the same method of calculation as was used for trypsin<sup>1</sup>, we obtain a value for the rate constant of inactivation by hydrogen atoms at 25° C ( $k_{\text{inact}}^{\text{H} \cdot + \text{RNase}}$ ) of  $3 \times 10^8$  l./mole sec at pH 6, and of  $6 \times 10^8$  l./mole sec at pH 1. By comparison the diffusion controlled limit for the collision between hydrogen atoms and RNase may be estimated (as was done by Braams<sup>12</sup> for the reaction between  $e_{\text{aq}}^-$  and RNase) as approximately  $3 \times 10^{10}$ /mole/sec. This is the theoretical maximum rate at which hydrogen atoms might add to RNase according to equation (1)

to yield a free radical. Not all hydrogen atoms added in this way lead necessarily to inactivation. The rate constant of inactivation now calculated is the overall rate of inactivation and may involve the action of either one or of a number of hydrogen atoms, reacting with various component amino-acids. These reactions of hydrogen atoms with RNase are in competition with the recombination of hydrogen atoms

with  $k$  (recomb.) =  $3 \times 10^{10}$  l./mole sec. Some information on the reactions of hydrogen atoms encountering RNase can be gained from the results on sulphhydryl and hydrogen sulphide formation. As shown in Fig. 1 and Table 1, more than four equivalents of sulphur-containing products ( $-\text{SH} + \text{H}_2\text{S}$ ) are formed for every RNase molecule inactivated both at pH 6 and also at pH 1, where  $k_{\text{inact}}$  increased twofold. While the ratio (inactiv.)/( $-\text{SH} + \text{H}_2\text{S}$ ) changes little, however, the ratio  $\text{H}_2\text{S}/-\text{SH}$  increases from 2.2 at pH 6 to 35 at pH 1.

Comparable results were obtained in the case of trypsin<sup>8</sup>. The ratio between molecules inactivated and sulphur equivalents formed was similar to that obtained by us. This led us<sup>8</sup> to consider the possibility that the correlation is connected with a specific distribution of the damage to the molecules, so that one does not have a population of molecules with random distribution of damage, some fully inactivated, some partly damaged, but the damage is concentrated at certain molecules, which are then completely inactivated, and also involves far-reaching damage to the disulphide linkages (of which there are four in RNase). This possibility was supported by the results on chymotrypsin<sup>3</sup>, where the analysis of the Lineweaver-Burk plots indicated that the action of hydrogen atoms resulted in complete inactivation of some molecules, without the formation (as is the case with ionizing radiations) of partially damaged molecules, with modified Michaelis constants but retaining some enzymatic activity.

Our attempts to obtain reliable Lineweaver-Burk plots in the case of RNase were unfortunately not successful, so that we have no comparable evidence in the present case.

Further comparison of the yields of sulphhydryl and hydrogen sulphide does, however, give some indirect support to these views. For the amino-acid cysteine<sup>2</sup> and the peptide, oxidized glutathione (unpublished observations), the rate constants of hydrogen atoms with  $\text{R}-\text{S}-\text{S}-\text{R}$  for the formation of sulphhydryl and hydrogen sulphide, respectively, at pH 6 were identical for the two

Fig. 1. Formation of sulphhydryl groups, evolution of hydrogen sulphide and inactivation of enzyme in  $3.7 \times 10^{-5}$  molar solutions of RNase at pH 6. Dose rate of hydrogen atoms approx.  $3 \times 10^{-4}$  moles/l. min. min.<sup>-1</sup>.

substrates within experimental error, and gave  $k(-SH) = 1 \times 10^6$  l./mole sec and  $k(H_2S) = 1 \times 10^8$  l./mole sec, so that the yields were in the ratio  $H_2S/-SH$  about 0.1. Investigation of the reaction of hydrogen atoms with the reduced forms of cysteine and glutathione gave for the rates of formation of  $R-S-S-R$  and hydrogen sulphide, respectively, the values  $k(\text{oxidation}) = 6 \times 10^8$  l./mole sec and  $k(H_2S) = 1 \times 10^8$  l./mole sec. For trypsin the ratio  $H_2S/-SH$  rose to unity at pH 6. It was suggested<sup>3,8</sup> that this specific increase in hydrogen sulphide can be correlated with the parallel damage to the aromatic amino-acid components, particularly tryptophan and tyrosine, as indicated by changes in the absorption and fluorescence spectrum.

Tryptophan is absent from RNase. The fluorescence spectrum (Fig. 2) is due to the six tyrosine residues in the molecule. As can be seen from Fig. 2, the percentage decrease in fluorescence, both at pH 6 and at pH 1 (25 per cent and 50 per cent, respectively), happens to be similar to the decrease in enzyme activity. This correlation may again be consistent with specific damage, concentrated on single molecules, in which the fluorescence due to all tyrosines has been eliminated.

Fig. 2. The effect of hydrogen atom treatment on the fluorescence spectrum of RNase, at pH 1 (A, untreated control and treatment with a total dose of approx.  $50 \times 10^{-5}$  moles/l. of hydrogen atoms; inactivation approximately 58 per cent) and at pH 6 (B, control; C, treated with total dose of approx.  $40 \times 10^{-5}$  moles/l. hydrogen atoms; inactivation approximately 25 per cent).

The difference absorption spectrum after hydrogen atom treatment at pH 6 is shown in Fig. 3. Similar results were obtained at pH 1. The well defined changes in limited regions in the spectrum, and the absence of a generalized background change, should be compared with the results of Smith and Adelstein<sup>13</sup> on the action of ionizing radiations (though at a higher percentage of inactivation). Consistent with the less specific action of ionizing radiations<sup>3,8,14</sup> involving particularly the oxidizing species  $OH\cdot$ , a broad background is seen in the difference spectrum of RNase treated with X-rays<sup>13</sup>. The position of the difference peaks is similar in our case to the X-ray results<sup>13</sup>, and different from the case of trypsin<sup>8</sup>, in which changes in the region due to tryptophan predominated.

Further information on the nature of the process leading to inactivation is provided by the fact that inactivation could not be reversed at all on admission of oxygen. When ribonuclease is reduced by some reagents, such as mercaptoethanol<sup>15</sup>, all four disulphide bonds are reductively opened. This reduced form is almost completely re-oxidized to the enzymatically active form when oxygen is admitted. Using other reducing agents such as borohydride, however, partial reversibility only is obtained. It is possible that the present results are connected with the fact that hydrogen atoms are of the family of one-electron equivalent reagents. Their action on an organic

Fig. 3. Difference spectrum after hydrogen atom treatment (total dose of hydrogen atoms approximately  $40 \times 10^{-5}$  moles/l.) at pH 6.

compound, in which stable states are separated by two electron equivalents, must result in the intermediate formation of free radicals<sup>16</sup>. The relevance of this to possible mechanisms of reductive inactivation of biologically interesting substrates, particularly DPN<sup>+</sup> (NAD), has been shown<sup>17</sup>, and borohydride indicated as a reagent operating by a mixed mechanism partly involving one-electron equivalent products. Possibly in the cases where almost full reversibility is obtained after reduction, intermediate free radicals are not produced, and the mechanism is in effect a two-electron equivalent process<sup>18</sup>.

The considerable irreversibility, observable already at low doses and low percentages of inactivation, is illustrated in Fig. 4, where the heating and cooling curves obtained at pH 6 and pH 1 are shown. Native RNase may be heated reversibly within the temperature range used at both pH values<sup>11</sup>, as shown by the control curves. Similar irreversible melting-annealing curves were obtained by Smith and Adelstein after treatment with ionizing radiations<sup>13</sup>. We do not know of a specific interpretation of the correlation between inflexion temperatures, spectroscopic changes and configuration of the macromolecule.

Table 2. SUMMARY OF THE RESULTS OF AMINO-ACID ANALYSIS ON SAMPLES TREATED WITH HYDROGEN ATOMS AT pH 6 AND pH 1

Not decreased at either pH (nor at high dose)

Lysine (10)  
Arginine (4)  
Asparagine + aspartic acid (10 + 5)  
Threonine (10)  
Glutamine + glutamic acid (7 + 5)  
Proline (4)  
Glycine (3)  
Alanine (12)  
Valine (9)  
Isoleucine (3)  
Leucine (2)

Slightly decreased (noticeably at high dose)

Histidine (4)

Decreased	At pH	Approximate percentage of decrease	
		6	1
1/2 Cystine	(8)	25	50
Methionine	(4)	25	60
Tyrosine	(6)	??	50
Phenylalanine		15	45

Dose of hydrogen atoms 40 and  $50 \times 10^{-5}$  molar respectively. Percentage of inactivation, 25 and 55 per cent respectively. Initial concentration of RNase,  $3.7 \times 10^{-5}$  molar. Numbers in brackets are number of component amino-acid in each molecule of RNase (ref. 18).

\* Control and treated samples at pH 6 both much lower than theoretical value.

Decrease relative to control approximately 20 per cent.

To locate the damage in the protein molecule, the effect of the hydrogen atom treatment on the individual amino-acid components was studied by complete amino-acid analysis. The detailed composition and to some extent the configuration of native RNases are known<sup>18</sup>. The amino-acid analyses were kindly carried out by Drs. Lester Smith and John Williams, of the Medical Research Council Laboratory for Molecular Biology, Cambridge. The results are summarized in Table 2. These included amino-acid analyses on untreated controls of pH 6 and pH 1, with

and without performate oxidation, as well as similar determination on samples treated at pH 1 with low ( $40 \times 10^{-5}$  moles/l.) and high ( $200 \times 10^{-5}$  moles/l.) doses of hydrogen atoms, and at pH 1 with a low dose ( $50 \times 10^{-5}$  moles/l.) of hydrogen atoms. The percentages of inactivation at the two low doses were approximately 25 per cent and 55 per cent, respectively. The high dose at which far-reaching inactivation and probably secondary attack on the products resulted was used to indicate the further course of the reaction. The results, given in Table 2, show that of the component amino-acids, only a few, those containing sulphur: half-cystine and methionine, and the aromatic amino-acids, tyrosine and phenylalanine, were considerably decreased, and histidine slightly decreased. The decrease in tyrosine in the amino-acid analysis parallels the decrease in fluorescence.

New product peaks were also observed, as well as apparent increases at the sites of some amino-acids, particularly alanine.

The results of the amino-acid analyses thus also point to the specificity of the damage in the molecule. They are also consistent with the view expressed previously<sup>3,8</sup>, that spatially correlated aromatic and sulphur-containing amino-acids may interact intramolecularly in determining the damage. Because methionine on reacting with hydrogen atoms (ref. 2 and unpublished observations) yields sulphydryl groups and particularly hydrogen sulphide much more slowly than does cystine, it is possible that the methionine affected in RNase is not the major source of the sulphydryl groups and hydrogen sulphide observed, which may originate largely from the half-cystines. The specific involvement of sulphur in the reaction will be discussed separately<sup>16</sup>.

The results thus confirm the correlation between inactivation of enzyme by hydrogen atoms and chemical effect on sulphur-containing and aromatic component amino-acids, as well as histidine, leaving most of the component amino-acids apparently unaffected. It is still not clear whether the damage is more or less randomly distributed among the population, or whether, as is consistent with the results, the population distribution shows a peak at two main points: one of largely unaffected and the other of highly damaged molecules, the latter group showing a correlation between disulphide opening and aromatic amino-acids affected. We hope to continue the investigation of this point.

As to the mechanism by which the encounter between hydrogen atoms and RNase results in such specific damage to components which are not necessarily the ones available on the surface of the protein molecules for primary encounter with hydrogen atoms, we assume<sup>7</sup> that after primary addition of a hydrogen atom to RNase an efficient process of irreversible material transfer, involving a hydrogen atom or probably an electron, will follow within the molecule. This mechanism of the concentration of damage on sensitive sites should be differentiated from mechanisms involving excitation energy transfer. Finally, the radical will be sited on those components, aromatic or containing sulphur<sup>16</sup>, with the greatest affinity. The reactivity of the radical may lead to further intramolecular reactions, as well as intermolecular ones including possibly dimerization of RNase radicals, until electron pairing is complete. When an electron accepting metal ion is present, as in ferricytochrome c (ref. 4), this will become the final site of the one-electron equivalent, so that free radical reactions do not ensue. Otherwise, divalent sulphur<sup>16</sup> and aromatic rings might prove the favoured site for radical formation, through proton equilibria and electron-equivalent transfer.

## Chemistry of Crossing-over

by

SHELDON WOLFF  
F. J. DE SERRES

Laboratory of Radiobiology, University of California Medical Center, School of Medicine, San Francisco, California, and Biology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee

The frequency of second division segregation of ascospore colour markers was used to demonstrate the effect of two chemicals (chloramphenicol and 5-fluorodeoxyuridine) on crossing-over in *Neurospora*. The effects of 5-fluorodeoxyuridine show that an impairment of DNA synthesis increases crossing-over.

ONE method by which it should be possible to investigate the chemistry of crossing-over is to use metabolic inhibitors to alter the chemical processes that occur at the time of genetic recombination. In the past, investigations of radiation-induced chromosome aberrations have shown that protein synthesis inhibitors prevent the repair or rejoining of breaks induced by radiation in  $G_1$  cells<sup>1</sup>, whereas the DNA synthesis inhibitor, 5-fluorodeoxyuridine (FUdR), does not<sup>2</sup>. These experiments have been interpreted as indicating that the bonds formed in the repair or rejoining of radiation-induced chromosome aberrations are in protein and not DNA. The mechanism of crossing-over is still unknown, but some models proposed for eukaryotes<sup>3</sup> suggest a mechanism quite similar to the breakage and reunion that occur after X-irradiation. If breakage of chromosomes, followed by rejoining or repair, occurs during crossing-over, then modification of the rejoining or repair processes with various metabolic inhibitors should affect the yield of recombinants. By using this experimental approach during meiosis it should be possible to determine the metabolic processes that are involved in meiotic recombination. In the present experiments we have shown that the inhibitor of DNA synthesis, 5-fluorodeoxyuridine, increases meiotic recombination as reported in brief previously<sup>4</sup>.

Metabolic inhibitors known to affect either DNA synthesis or protein synthesis were tested for an effect on crossing-over with *Neurospora crassa*. Those tested were chloramphenicol, an inhibitor of protein synthesis<sup>5</sup>, and 5-fluorodeoxyuridine, an inhibitor of DNA synthesis<sup>6</sup>. The effect of these compounds on crossing-over was assayed by determining the frequency of second division segregation for an ascospore colour marker (*asco* or *lys*<sup>-5</sup>; FGSC No. 405) in a cross with wild-type (74-OR23-1A; FGSC No. 987). Crosses were made at room temperature (~24° C) in 125 ml. Erlenmeyer flasks containing filter paper cones and 25 ml. of liquid synthetic crossing medium<sup>7</sup> supplemented with DL-lysine (100  $\gamma$ /ml.). The flasks were inoculated with the wild-type strain as the female parent. After the protoperithecia had formed, conidia of the *asco* strain (used as the male parent) and solutions of the chemicals were added simultaneously.

To treat with chloramphenicol a solution of 'Millipore' filter sterilized chloramphenicol was added to the flasks to give a final concentration of 300 or 600  $\gamma$ /ml. in the crossing medium. (Concentrations of 600  $\gamma$ /ml. and greater had been found to give at least a 25 per cent decrease in the linear growth rate of the wild-type strain.) 5-Fluorodeoxyuridine, when used, was added alone or in combination with uridine to give final concentrations of 10<sup>-4</sup>, 5  $\times$  10<sup>-5</sup>, or 10<sup>-5</sup> molar 5-fluorodeoxyuridine and 10<sup>-4</sup> molar uridine. Uridine was added to obviate any possible effects of incorporation of fluorouracil (a breakdown product of 5-fluorodeoxyuridine) into RNA. Treatment with 10<sup>-4</sup> molar uridine was also tested as a control.

Duplicate or triplicate crosses were made for each treatment. Perithecia were dissected in a viscous methyl cellulose solution, and the percentage of second division segregation for *asco* was determined for each of the treatments by analysing 400 asci under a dissecting microscope.

The results in Table 1 show that only 5-fluorodeoxyuridine (either alone or in combination with uridine) gives a significant change in the frequency of second division segregation. No significant effect of the concentration of 5-fluorodeoxyuridine was found over the range of 10<sup>-5</sup>–10<sup>-6</sup> molar either with or without 10<sup>-4</sup> molar uridine. The

Table 1. PERCENTAGE OF SECOND DIVISION SEGREGATION AFTER TREATMENT WITH METABOLIC INHIBITORS

Experiment	Treatment	No. of second division asci	Percentage of second division asci

" " 4 versus 1 = 1.22  $P$  approximately 0.25.

Four hundred asci were used in each case.

results of the present experiments tend to implicate DNA synthesis in meiotic recombination and indicate that an impairment of this process gives an 18 per cent increase in crossing-over. We do not know whether the effect of 5-fluorodeoxyuridine that leads to increased crossing-over occurs at the time of chromosome duplication (the *S* period of the cell cycle), or whether it occurs after duplication and pairing of homologous chromosomes at the time of cytologically observable crossing-over.

No effect was found with chloramphenicol. This does not necessarily imply, however, that inhibition of protein synthesis has no effect on the frequency of crossing-over in *Neurospora*, for we have no direct evidence that the inhibition of linear growth rate obtained with high concentrations of chloramphenicol is caused by a general inhibition of protein synthesis. Furthermore, we have found that puromycin (another protein synthesis inhibitor) did not affect linear growth rate of *Neurospora*.

5-Fluorodeoxyuridine has been found to break chromosomes in higher plants<sup>6</sup>. Such breakage has been postulated to occur either at the end of DNA synthesis (the *S* period)<sup>8</sup> or in *G*<sub>2</sub>, the post-synthetic interphase<sup>2</sup>. The effect of 5-fluorodeoxyuridine, however, is so drastic that many breaks are usually produced in a cell and these do not rejoin. Such an effect, therefore, should not lead to recombination but to genetic loss and death of the affected cells. In *Neurospora* the presence of chromosome aberrations in a cross can be detected by an increase in the percentage of ascospore abortion (light tan or colourless spores). An effect of this type would not be readily detectable in the cross of *asco* and wild-type because all *asco* ascospores are colourless. Evidence for this type of effect in *Neurospora* was sought by analysing a cross of two wild-type strains [74-OR23-1A (FGSC No. 987) and 74-OR8-1a (FGSC

No. 988)] showing a very low percentage of aborted ascospores<sup>9</sup>. None of the chemical treatments increased the percentage of ascospore abortions over the 0.8 per cent found in the control cross. This test suggests that, in *Neurospora*, the concentrations of 5-fluorodeoxyuridine that give an increase in crossing-over do not give any detectable chromosome aberrations.

It is interesting to note that both 5-fluorodeoxyuridine and mitomycin C, which are known to inhibit DNA synthesis in fungi<sup>10,11</sup>, have been found to increase the frequency of somatic recombination in *Ustilago maydis*<sup>11,12</sup>. The present experiments, in which an inhibitor of DNA synthesis increases recombination but a protein-synthesis inhibitor does not, tend to implicate DNA synthesis in genetic recombination during meiosis. They do not necessarily imply, however, that crossing-over in eukaryotes occurs solely in DNA to the exclusion of protein.

This research was sponsored by the U.S. Atomic Energy Commission under contract with the Union Carbide Corporation.

*Streptomyces prasinus* is found to produce at least five members of a new family of antibiotics, the prasinomycins. These are of high molecular weight and active *in vitro* against Gram-positive bacteria. Single subcutaneous doses provide prolonged protection to mice against *Streptococcus pyogenes*.

A FAMILY of new antibiotics, the prasinomycins, was found to be produced by a streptomycete isolated from a sample of soil collected in Colorado. The organism has been identified as *Streptomyces prasinus*, a member of the green spore colour series of streptomycetes. Contrary to a report of Ettlinger *et al.*<sup>1</sup>, *S. prasinus* does produce an antibiotic, as do other members of this spore colour series, for example *S. hirsutus* and *S. prasinopilosus*. The antibiotic producing activity is, however, specific to the strain because not all cultures examined showed activity.

The cultures were maintained on tomato paste-oatmeal agar slants. When needed, germinator cultures were grown in 15 g soybean meal, 15 g dehydrated mashed potato, 50 g glucose, 0.005 g COCl<sub>2</sub>·2H<sub>2</sub>O, 10 g calcium carbonate and 1 l. of distilled water. After incubation at 25° C for 4 days, 5 ml. was used to inoculate 100 ml. of the fermentation medium in 500 ml. Erlenmeyer flasks.

The fermentation medium consisted of 60 g soybean meal, 50 g glucose, 1 g disodium phosphate, 10 g calcium carbonate and 1 l. of distilled water. The fermentation flasks were incubated at 25° C for 7 days. All incubations were carried out on a rotary shaker, operating at 280 r.p.m. with a 2 in. throw. After production of the antibiotic and its isolation, both agar diffusion and tube dilution bioassays with *Staphylococcus aureus* 209 P were carried out.

Although the activity was present in both mycelium and filtrate at the time of collection, all the activity could be recovered with the mycelial cake by acidification of the culture broth to pH 2 before filtration. The filter cake was extracted with methanol and the extract neutralized to pH 7. The aqueous suspension obtained after evaporation of the methanol was acidified to pH 2 and extracted with chloroform. The chloroform extract, which contained most of the activity, was concentrated

under vacuum to a thick oil and the crude antibiotic precipitated by the addition of ten volumes of acetone. The light tan amorphous powder so obtained showed a minimum inhibitory concentration against *S. aureus* 209 P of 0.15 µg/ml. in a two-fold tube dilution assay. The acetone powder was dissolved in ten times its weight of water, adjusted to pH 9 with sodium hydroxide and washed with *n*-butanol. The aqueous phase was adjusted to pH 5 with hydrochloric acid and washed again with *n*-butanol. The strongly acidic antibiotic was finally liberated by adjustment of the aqueous phase to pH 2, and the resulting free acid extracted into *n*-butanol. The butanolic solution was neutralized with sodium hydroxide and the mixture evaporated to dryness to obtain the crude sodium salt of prasinomycin. At this point it was found that the antibiotic in aqueous solution did not pass through a semi-permeable 'Cellophane' membrane. The crude sodium salt was therefore dialysed to effect further purification. The product obtained had a minimum inhibitory concentration of 0.04 µg/ml. in the *S. aureus* 209 P tube dilution assay. The free acid could be conveniently prepared by removal of the sodium ions by stirring an aqueous solution with 'Dowex 50' (H<sup>+</sup> form).

Considerable difficulty was experienced in finding a suitable partition paper chromatography system which would resolve the antibiotic mixture. It was subsequently found, however, that if doubly acid washed paper (Munktells No. S-302) was used with suitable basic solvent systems resolution of the antibiotic mixture into several bioactive components could be effected. The stationary phase was placed on this paper by dipping it into a mixture of acetone and lower phase of the solvent system (2:1 by volume) and allowing the acetone to air dry at room temperature (2-3 min). The solvent system, *n*-butanol-pyridine-water (4:1:4 by volume), resolved the antibiotic mixture into five bioactive components which could be detected by placing the air-dried chromatogram on the surface of a nutrient agar plate seeded with *Staphylococcus aureus*<sup>2</sup> or by spraying the chromatogram with a 0.001 per cent solution of rhodamine B in 0.25 molar potassium monohydrogen phosphate<sup>3</sup>. The latter technique resulted in white spots on a pink background. The sensitivity of the bioautographic method is about 0.01-0.05 µg. Because of its shorter development time, a *n*-propanol-*n*-butanol-0.2 molar *N*-ethylmorpholine system (2:3:4 by volume) was also found to be useful, although the resolution was not so good (Table 2).

Three of the five components of the antibiotic mixture were isolated by countercurrent distribution in a *n*-propanol-*n*-butanol-0.2 molar *N*-ethylmorpholine system (2:3:6 by volume) under nitrogen. After a thousand transfers, tubes 270-290, which contained a single bioactive component, were removed and combined to give prasinomycin C. After an additional five hundred transfers, tubes 200-240 and tubes 280-320 yielded prasinomycins A and B, respectively. The apparent homogeneity of each component was confirmed by the paper chromatography and the detection techniques already described. To isolate the components as free acids, the solutions were evaporated under vacuum to dryness, taken up in water and treated with 'Dowex 50' ion exchange resin. After filtering off the resin, the solutions were freeze dried and the residue precipitated from methanol by the addition of ethyl acetate to yield approxi-

§ Determined on hydrated forms.

mately equal amounts of prasinomycins A, B and C as colourless, amorphous compounds. Prasinomycins D and E were present in relatively small amounts and have not yet been isolated in pure form.

These antibiotics appeared to have a high molecular weight because they did not pass through a 'Cellophane' membrane on dialysis. In addition, a determination of molecular weight in aqueous buffered solution using an analytical ultracentrifuge<sup>4</sup> gave a value of about 31,000 (Table 1). This value apparently represents an aggregated form, however, because molecular weights in the range of 1,600-1,850 were found for the hydrated forms of the free acids when the determinations were carried out in ethanol solution. The molecular weights determined by the ultracentrifugation method appeared to be highly dependent on the environment of the compounds in solution. For example, after the addition of a small amount of pH 7 phosphate buffer to the ethanol solution, values of 2,100-2,300 were obtained for the molecular weights of the resulting sodium salts. In all the determinations a small amount of a higher molecular weight component (7,200-7,400) could be detected which prevented the calculation of an accurate value for the major component. It is not known whether this minor component represents an impurity or yet another aggregated form. The neutral equivalent of each antibiotic determined by titration with base (Table 1) indicated that several acidic functions were present. These antibiotics are presumably diesters of phosphoric acid which would account for their strongly acidic character. Other acidic functions apparently reside in carboxyl groups because conversion of the acids to the sodium salts results in decreased absorption at 5.80µ (COOH) and increased absorption at 6.10-6.25µ and 7.0µ, characteristic for the transformation of a carboxylic acid to its carboxylate anion. The infra-red spectra of prasinomycins A, B and C are very similar. They all exhibit a strong band centred at 3.0µ (O-H, N-H) as well as absorption at 5.84µ (COOH),

6.0-6.05µ ( $\begin{array}{c} \text{O} \\ \parallel \\ \text{C-NH-} \end{array}$ ), and 6.45µ (N-H). The infra-red spectra indicated the presence of amide groups, and acid hydrolysis liberated acetic acid suggesting the presence of *N*-acetyl functions. All the antibiotics showed absorption in the ultra-violet in the region of 257 mµ (sodium salts), but prasinomycin B was characterized by a much higher extinction coefficient than either A or C (Table 2). The three compounds rapidly formed hydrates on exposure to the atmosphere. The analytical data presented in Table 1 were obtained on the anhydrous forms after drying at 80° C under vacuum. The elementary analyses for the prasinomycins suggest that these antibiotics have empirical formulae in the range (C<sub>62-74</sub>H<sub>98-130</sub>N<sub>5-6</sub>O<sub>32-40</sub>P).

Table 2. PHYSICAL PROPERTIES OF THE PRASINOMYCINS

\* *n*-Butanol, pyridine, water (4:1:4 by volume).

† *n*-Propanol, *n*-butanol, 0.2 molar *N*-ethylmorpholine (2:3:4 by volume).

‡ *n*-Propanol, *n*-butanol, 0.1 molar *N*-ethylmorpholine (2:3:6 by volume). Countercurrent distribution run in nitrogen atmosphere.

Acid hydrolysis of prasinomycin *A* gave equivalent amounts of D-glucosamine, 6-deoxy-D-glucosamine and glycine. Hydrolysis of prasinomycins *B* and *C* also gave the same two amino sugars in equivalent amounts but only a trace of glycine. The amino sugars were separated from the hydrolysis products by ion exchange chromatography on 'Dowex 50' (H<sup>+</sup>) eluting with a gradient of 0.2 normal to 2 normal hydrochloric acid. Glucosamine was isolated as the crystalline hydrochloride and identified by comparison with an authentic sample. The 6-deoxy-D-glucosamine was acetylated to give a mixture of  $\alpha$ - and  $\beta$ -tetraacetyl-6-deoxy-D-glucosamine and identified by comparison with an authentic mixture of the  $\alpha$  and  $\beta$  forms. Further efforts to elucidate the structures of these antibiotics are in progress.

The antibiotic mixture, as well as the individual components, are active *in vitro* against Gram-positive bacteria and *Mycobacterium bovis* B.C.G. They have relatively little activity against yeasts, fungi and Gram-negative bacteria. The individual components have the same order and magnitude of activity as the mixture. The prasinomycins are not cross-resistant with penicillin, with any members of the tetracycline family, or with streptomycin, neomycin, chloramphenicol, novobiocin, bacitracin, resistocetin, erythromycin, oleandomycin, carbomycin or methymycin. The *in vivo* effectiveness of the antibiotic mixture when given subcutaneously is

shown by a 50 per cent protective dose of approximately 0.5 mg/kg against *Streptococcus pyogenes* C<sub>203</sub>. No protection is granted to mice when the antibiotic mixture is given *per os*. A remarkable property of the prasinomycin mixture is the prolonged protective effect obtained with a single subcutaneous dose. Protection was still afforded to mice infected with *Streptococcus pyogenes* C<sub>203</sub> 28 days after administration of the antibiotic.

We thank Professor Richard Kuhn for an authentic sample of tetraacetyl-6-deoxy-D-glucosamine. We also thank Dr. J. Kirschbaum for determination of molecular weights, W. Trejo for the identification of the organisms, J. Alicino for elementary analyses, and H. Basch for the biological assays.

*Note added in proof.* Since submission of this manuscript, two other research groups have reported the isolation of antibiotics which appear to be related to prasinomycin: (a) Moenomycin (Wallhauser, K. H., *et al.*, *Antimicrobial Agents and Chemotherapy*, 735-6; 1965); (b) Antibiotic 11837RP (Mancy, D., *et al.*, *Abstr.*, *Ninth Inter. Congr. Microbiol.*, Moscow, July 24-30, 1966, p. 165).

## Mathematical Interpretation of Heart Kymography

by

G. JAŚKIEWICZ

Wrocław Technical University, Wrocław

L. SAMOCHOWIEC

Department of Pharmacology, Silesian Medical Academy, Katowice

A kymograph—a revolving drum carrying smoked paper—is frequently used to record variations of heart action. Mathematical analysis of the kymograms will provide information about the action on the organ of drugs such as cardiac glycosides.

THE trace of a kymograph can be analysed in a number of ways. The problem is often solved very simply by calculating the percentages, for example, of the increase or decrease in the amplitude of the curve, of the reaction velocity, or of the duration of the reaction. In this article we shall show how a mathematical formulation of the results can be obtained when the influence of cardiac glycosides on the isolated heart of the rat is investigated.

Tests were carried out on thirty male Wistar rats according to the method of Langendorff as modified by Wiegand<sup>1</sup>. After a period of adaptation lasting 2-5 min, the effects on the beat of the isolated heart of a single 10  $\mu$ g dose of strophanthine *g*, digitoxine and convalatoxine were investigated. The dose was administered in a volume of 0.1 ml. of perfusing fluid through a polyethylene cannula inserted into the aortic arch. A further

0.1 ml. of the perfusing solution was used to advance the drug. Coronary outflow was also recorded.

The "envelopes" of the kymograms of the action of the heart after a single dose of a drug, using the Langendorff method, can be approximated by curves which are satisfied by equations of the type (1)-(5)

$$A = [C_1 + C_2(t - t_0)] \exp [-r(t - t_0)] + C_3 \quad (1)$$

where  $A$  is the amplitude of the envelope,  $t$  is the time of the contraction,  $t_0$  is the time at which the drug was administered, and  $C_1$ ,  $C_2$ ,  $C_3$  and  $r$  are constants characterizing the given course.

When  $t = t_0$ , the value of the amplitude when the drug is administered is  $A_0 = C_1 + C_3$ . For  $t \rightarrow \infty$ —that is in a time sufficiently remote from the moment the drug is adminis-

Fig. 1. Recording of the action of the heart after injecting a single 10  $\mu$ g dose of strophanthine.

Fig. 2. Recording of the action of the heart after injecting a single 10 µg dose of digitoxine.

Fig. 3. Recording of the action of the heart after injecting a single 10 µg dose of convallatoxine.

tered—the envelope amplitude returns to normal and is usually established on a different level from that observed before the drug was administered. From equation (1), when  $t \rightarrow \infty$ , the final level  $A_k = C_2$ , and thus  $C_1 = A_0 - A_k$ . Because  $r > 0$ , the curve satisfied by equation (1) has a maximum when  $C_2 > 0$ .

The time derivative of curve (1) for  $t = t_{\max}$ , where  $t_{\max}$ —the moment where the maximum amplitude appears—equals 0, thus

$$\frac{dA}{dt} \Big|_{t=t_{\max}} = \{-C_1 r + C_2[1 - (t_{\max} - t_0)r]\} \exp[-r(t_{\max} - t_0)] = 0$$

$$\text{whence} \quad r = \frac{C_2}{C_1 + C_2(t_{\max} - t_0)} \quad (2)$$

Substituting for  $C_1$ ,  $C_2$  and  $r$  in equation (1) we obtain

$$A = [(A_0 - A_k) + C_2(t - t_0)] \exp \left[ -\frac{C_2(t - t_0)}{(A_0 - A_k) + C_2(t_{\max} - t_0)} \right] + A_k \quad (3)$$

When, after returning to the "norm", the final level of the envelope equals the initial level (normal rate), that is, when  $A_k = A_0$ , we obtain

$$A = C_2(t - t_0) \exp \left[ -\frac{t - t_0}{t_{\max} - t_0} \right] + A_0 \quad (4)$$

Then, for  $t = t_{\max}$ , the following value of the maximum amplitude is obtained  $A = A_{\max \text{ norm}}$ , and from equation (4)

$$\frac{A_{\max \text{ norm}} - A_0}{t_{\max} - t_0} = \frac{C_2}{e} = \alpha \quad (5)$$

where  $\alpha$  is constant for the given normal kymogram course. This constant can be termed a "coefficient of inotropic reactivity", and is dependent on the character, biological activity and dosage of the drug administered, as well as on the properties and "condition" of the heart

examined. Substituting the coefficient  $C_2$  obtained from equation (5) in equation (3)

$$A = [(A_0 - A_k) + \alpha e(t - t_0)] \exp \left[ -\frac{\alpha e(t - t_0)}{(A_0 - A_k) + \alpha e(t_{\max} - t_0)} \right] + A_k \quad (6)$$

If the course proceeds according to equation (6), the reactivity coefficient will be connected with the proportion

$$\frac{A_{\max} - A_0}{t_{\max} - t_0}$$

by a complex equation.

If  $A = A_{\max}$  and  $t = t_{\max}$  are substituted in equation (6) we obtain.

$$\frac{A_0 - A_k}{A_{\max} - A_k} + \alpha e \frac{t_{\max} - t_0}{A_{\max} - A_k} = \exp \left[ \frac{1}{1 + \frac{A_0 - A_k}{\alpha e(t_{\max} - t_0)}} \right] \quad (7)$$

We encountered considerable difficulty in the analytical determination of the coefficient  $\alpha$  from equation (7). Because of this we decided to use a graphical method in order to establish the value of this coefficient, that is, to compare the left and the right hand sides of equation (7). Assuming that  $y$  has the value of the left hand side of equation (7), a straight line is obtained; however, if it has a value equivalent to the right hand side a curve is produced. The point of intersection of the curve and the straight line gives the value of the inotropic reactivity coefficient  $\alpha$  for the course of equation (6).

As has already been established, it is easy to determine all the coefficients of equation (1) or, synonymously, the coefficients of equation (6). Thus the values  $A_0$ ,  $A_k$  and  $t_{\max}$  can be obtained directly from a kymograph as indicated and the coefficient from the intersection of the curve and line using components of equation (7). It must be emphasized, however, that the use of this equation would require that the value of  $A_{\max}$  be determined. By substituting the values  $A_0$ ,  $A_k$  and  $t_{\max}$  in equation (6), we obtain an approximate analytical picture of the

Fig. 4. Calculations for chart on Table 1.

Table 1

$A_0 = 2.4$  cm;  $A_k = 1.45$  cm;  $A_{max} = 3.85$  cm;  $t_{max} = 10$ ;  $t_0 = 4$ .

$$\exp \left[ \frac{1}{1 + \frac{A_0 - A_k}{\alpha e (t_{\max} - t_0)}} \right] = \exp \left[ \frac{1}{1 + \frac{0.95}{\alpha e}} \right]$$

changed amplitude and the heart beat, which results from the effects of an administered drug.

The frequency of the heart beat after a single dose of glycoside drugs can be analysed in a similar fashion. The changes in frequency over the kymogram course determined from an analytical equation similar to equation (6)

$$f = [(f_0 - f_k) + \alpha_f e (t_{extr} - t_0)] \exp \left[ - \frac{\alpha_f e (t - t_0)}{(f_0 - f_k) + \alpha_f e (t_{extr} - t_0)} \right] + f_k \quad (8)$$

where  $f_0$  is the frequency of contractions at the moment of administering the drug,  $f_k$  is the frequency of contractions after the action of the heart has settled down,  $t_0$  is the moment at which the drug is administered,  $t_{extr}$  is the moment at which the maximum number of contractions occurs and  $\alpha_f$  is the chronotropic reactivity coefficient. This coefficient is similar to the inotropic reactivity coefficient

$$\alpha_f = \frac{f_{extr \text{ norm}} - f_0}{t_{extr} - t_0} \quad (9)$$

where  $f_{extr \text{ norm}}$  is the maximum frequency of vibration of normal heart action, that is one in which the frequency of vibration returns to normal ( $f_k = f_0$ ).

The chronotropic reactivity coefficient can be determined from equation similar to equation (7)

$$\frac{f - f_0}{f_{extr} - f_k} + \alpha_f e \frac{t_{extr} - t_0}{f_{extr} - f_k} = \exp \left[ \frac{1}{1 + \frac{f_0 - f_k}{\alpha_f e (t_{extr} - t_0)}} \right] \quad (10)$$

where  $f_{extr}$  is the maximum number of contractions during the whole kymogram course.

The changes in velocity of the coronary outflow during the action of a heart which had been stimulated by a single dose of the drug were fairly similar for all the drugs which we tested. As shown in Fig. 5, this can also be described by an equation similar to equation (6)

$$Q = [(Q_0 - Q_k) + \alpha_Q e (t_{extr} - t_0)] \exp \left[ - \frac{\alpha_Q e (t - t_0)}{(Q_0 - Q_k) + \alpha_Q e (t_{extr} - t_0)} \right] + Q_k \quad (11)$$

where  $Q_0$  is the velocity of the coronary outflow at the time when the drug was administered,  $Q_k$  is the velocity of the coronary outflow after the action of the heart has settled down,  $t_0$  is the moment at which the drug was administered,  $t_{extr}$  is the time at which maximum velocity of the coronary outflow occurs, and  $\alpha_Q$  is the coefficient of the flow reactivity defined in the same way as the inotropic reactivity coefficients.

Thus

$$\alpha_Q = \frac{Q_{extr \text{ norm}} - Q_0}{t_{extr} - t_0} \quad (12)$$

where  $Q_{extr \text{ norm}}$  is the maximum velocity of the coronary outflow when normal—that is when the velocity of the coronary outflow returns to normal.

Fig. 5. Recording and envelope of a coronary outflow after administering 10  $\mu$ g digitoxine.  $Q$ , Value of the coronary outflow;  $t$ , time.

The reactivity coefficient of the flow can be determined from an equation similar to (7)

$$\frac{Q_0 - Q_k}{Q_{extr} - Q_k} + \alpha_Q e \frac{t_{extr} - t_0}{Q_{extr} - Q_k} = \exp \left[ \frac{1}{1 + \frac{Q_0 - Q_k}{\alpha_Q e (t_{extr} - t_0)}} \right] \quad (13)$$

where  $Q_{extr}$  is the maximum velocity of the coronary outflow for the kymogram course.

If the computed values of the coefficients  $\alpha$ ,  $\alpha_f$  and  $\alpha_Q$  are substituted in equations (8), (9) and (11) from equations (7), (10) and (13) we obtain strict analytical expressions for  $A$ ,  $f$  and  $Q$  as functions of time  $t$ . The remaining coefficients of these equations, for example,  $A_0$ ,  $A_k$ ,  $t_{max}$  and  $t_0$ , can easily be read from the diagrams. By examining several such diagrams for different hearts, various drugs and dosages, we can determine whether a relationship exists between the individual coefficients, and if so to what extent it holds true. It would be invaluable to know, for example, what relationship exists between  $A_0$ ,  $A_k$ ,  $t_{max}$ ,  $t_0$  and  $\alpha$ . It would also be interesting to find out whether, for example, the  $A_k$ ,  $t_{max}$  and  $\alpha$  depend on the primary working conditions of the heart, that is on  $A_0$ , and  $t_0$ , or which of the quantities.  $A_k$ ,  $t_{max}$  and  $\alpha$  depend on the nature and conditions of the heart, and which depend on the dosage of the drug

administered. Furthermore, it would be useful to know the nature and the extent of any such dependencies.

Once this has been done some coefficients can then be eliminated from equations (6), (8) and (11). If these relationships do exist, and they can be defined by analytical formulae, this elimination might be achieved by analytical means. It is possible, however, that these relationships can be defined only by diagrams. In this event equations (6), (8) and (11) could be used in conjunction with the diagrams.

The components discussed here will probably differ according to the drugs used. It should therefore be made clear that the final forms of equations (6), (8) and (11), as well as the diagrams mentioned, will, of course, differ from one drug to another.

Experiments carried out so far show that the coefficients of inotropic reactivity  $\alpha$ , chronotropic reactivity  $\alpha_f$  and flow reactivity  $\alpha_Q$  are constant for hearts of similar properties and condition, treated with equal amounts of the same drug. The value of these coefficients for a similar amount of the same drug can be determined statistically by investigating the effect of the drug on a large number of hearts. Here deviations from the normal values of these coefficients would indicate that the heart is in a pathological condition. This value would be an objective, strictly mathematically determined quantity. For different amounts of the same drug the values of the coefficients  $\alpha$ ,  $\alpha_f$ ,  $\alpha_Q$ , will usually be different. By treating the heart with different doses of drugs and by performing an adequate number of tests we would obtain dependencies

$$\alpha, \alpha_f, \alpha_Q = (\text{dose of drug}) \quad (14)$$

Determination of these dependencies will make it possible to foresee the behaviour of the heart when the amount of drug administered is altered. This will facilitate a strict determination of the amount of drug permissible and most effective for each heart examined. Many dependencies of type (14) will be obtained for different drugs and it should be possible to establish a set of curves determining the effectiveness of various drugs and their eventual quantitative equivalent.

The curve of type (14) will also enable the interrelation between coefficients  $\alpha$ ,  $\alpha_f$ ,  $\alpha_Q$  to be determined, and that between equations (6), (8) and (11)—in other words, between the amplitude  $A$ , of the frequency of contractions  $f$  and the speed of the coronary outflow  $Q$  at every moment of time  $t$ . Determination of this interrelation would be desirable for an interpretation of the phenomena occurring in the heart. It would facilitate the building up of a mathematical model of the heart.

Finally, we emphasize that the equations presented here are, as we mentioned earlier, only approximate and do not pretend to give a full and complete explanation of the phenomena occurring in the heart under the influence of drugs.

## Fertile Life of Rabbit Spermatozoa in Rat Uterus

by

J. M. BEDFORD\*

Department of Physiology,  
Royal Veterinary College,  
London, N.W.1

Injection of rabbit spermatozoa into the uterus of rat has demonstrated a prolongation of the fertile life of the sperm, sometimes to almost twice that in the rabbit uterus.

THERE is considerable variation between different mammals in so far as the viability of spermatozoa within the female is concerned. Chang<sup>1</sup> has raised the question of the relative importance of the inherent qualities of the spermatozoon, on the one hand, and the characteristics of the female environment, on the other, in the determination of the fertile and motile life of spermatozoa after their entry into the female. Little is yet known, however, of the relationship which exists between spermatozoa and the secretions of the female tract to which they are exposed. Although the integrity of spermatozoa is maintained within the male tract for a period of several weeks<sup>2,3</sup>, spermatozoa remain viable within the female for a much shorter period, which is best measured in hours. In the male and the female, however, the viability of spermatozoa as judged by motility cannot necessarily be taken as an indication of functional competence, because in both of these situations the ability to fertilize is lost well before the capacity for progressive movement. Spermatozoa have been shown to retain their motility for a significantly longer period than their fertilizing ability in the female tract of the mouse<sup>4</sup>, rat<sup>5,6</sup>, guinea-pig<sup>5,7</sup> and sheep<sup>8</sup>. In the rabbit, motile spermatozoa

have been found within the uterus and Fallopian tubes as late as 50 h after insemination<sup>9</sup>. Yet virtually no rabbit spermatozoa remain fertile in the female tract for longer than 30–32 h<sup>2,9,10</sup>, and as judged by litter size, the fertility of many spermatozoa begins to deteriorate some 10 h earlier than this<sup>2</sup>.

In the hope of clarifying further the specificity of the relationship which exists between competent spermatozoa and the environment of the female reproductive tract, rabbit spermatozoa from the cauda epididymidis were incubated in the uterus of the oestrous ferret, cat, guinea-pig and rat. It soon became apparent that the uterine environment in the ferret, cat or guinea-pig is relatively unfavourable to rabbit spermatozoa<sup>14</sup>. The uterine milieu in the oestrous rat, on the other hand, has proved to be a highly suitable climate for the survival of rabbit spermatozoa. It is the purpose of this article to discuss the effect of this favourable heterologous uterine environment on the motile and fertile life of rabbit spermatozoa.

Oestrous and pro-oestrous rats, selected on the basis of their vaginal cytology, were anaesthetized with ether and the uterus was exposed through a ventral mid-line incision. Only those females whose uterine horns were filled with fluid were used as recipients for the rabbit spermatozoa. Spermatozoa taken from the cauda epi-

\* Present address: The Worcester Foundation for Experimental Biology, Shrewsbury, Massachusetts, U.S.A.

didymidis in adult male rabbits were suspended in Hanks solution, and between 4-8 million spermatozoa in 0.03 ml. were injected through the uterine wall immediately above the cervix; the uterus was then ligatured with linen thread to prevent loss of fluid. Usually four to six rats were used in each experiment as recipients of aliquots from a single sperm sample. The spermatozoa were recovered subsequently by withdrawal of the uterine fluids at various times up to 48 h later. The recovered sperm samples were assessed subjectively using a Fuchs-Rosenthal cytometer, and were considered positive if more than 15 per cent of the spermatozoa in the sample showed vigorous progressive motility.

The results of the sperm survival experiments are summarized in Table 1. In general, the survival of rabbit spermatozoa in the rat uterus, as judged by motility, was similar to that in the rabbit uterus. In a few cases, appreciable numbers of rabbit spermatozoa still showed good motility when recovered after 48 h in the rat uterus, but in the majority of instances rabbit spermatozoa survived for a somewhat shorter period in these conditions. Table 1 does not bring out the point that different females whose uteri were filled with fluid showed considerable variation in their respective abilities to support the motility of spermatozoa within the uterus. Thus, at 48 h, only one animal in each group of four to six comparable females possessed highly motile spermatozoa in the uterine flushings. In the others the spermatozoa were either lying free but immotile, or had been ingested by uterine leucocytes. Taken overall, there was a definite difference between apparently similar uterine environments in their ability to support the motility of spermatozoa.

Table 1. SURVIVAL OF RABBIT SPERMATOZOA IN THE FLUID-FILLED UTERI OF OESTROUS RATS

Time in rat uterus (h)	No. of motile spermatozoa samples*
12-18	32/40 (80%)
18-24	22/30 (73%)
24-30	12/18 (66%)
30-36	9/15 (60%)
36-42	7/18 (39%)
42-46	8/26 (30%)
46-48	4/23 (16%)

Numbers in parentheses are percentages of motile spermatozoa samples.

\* Samples containing more than 15 per cent motile spermatozoa.

After examination of their motility, the fertilizing ability of rabbit spermatozoa recovered from the rat uterus was assessed in the following way: 0.03 ml. aliquots of rat uterine fluid containing between 150 and 300  $\times$  10<sup>3</sup> rabbit spermatozoa were inseminated directly into the ampulla of the Fallopian tube in oestrous rabbits<sup>11</sup>. An ovulation injection of human chorionic gonadotrophin ('Pregnyl', Organon) was given to the rabbit either soon before or after tubal insemination. The tubal ova were recovered 1-3 days after ovulation, and were examined for evidence of fertilization. The total fertile life of the spermatozoa in these experiments was estimated to be the length of time for which the spermatozoa were kept in the rat, plus the duration of their residence in the rabbit Fallopian tube before ovulation. The results of the fertility trials are shown in Table 2, the data of which refer only to those experiments carried out after a total of more than 32 h, that is, beyond the normal fertile life of rabbit spermatozoa in the rabbit female tract.

It is evident that after residing previously in the rat uterus, the fertile life of motile rabbit spermatozoa can be extended significantly, in some cases to almost twice the maximum which obtains normally in the rabbit (Fig. 1). Good motile rabbit sperm samples kept in the rat and rabbit for a total of about 45 h always fertilized a majority of ova, and significant numbers of supplementary and supernumerary spermatozoa were found in association with these fertilized ova. After this time, the numbers of spermatozoa about the ova diminished, but the fertilization rate remained high until 50 h, after which

it showed a general decline. Although motile rabbit spermatozoa collected from the rat after 48 h were able to fertilize 80 per cent of ova when placed in the rabbit Fallopian tube only 3 h before ovulation (No. 9), no fertilization was obtained with comparable samples (Nos. 15-17) inseminated similarly 11 h before ovulation.

Table 2. FERTILE LIFE OF MOTILE RABBIT SPERMATOZOA RECOVERED FROM THE RAT UTERUS

Animal No.	Hours of incubation before fertilization In rat uterus	In rabbit oviduct	Total	Percentage of ova fertilized
1	20	12	32	80
2	22	11	33	100
3	24	12	36	80
4	33	11	44	100
5	33	11	44	87.5
6	35	12	47	100
7	39	11	50	70
8	39	11	50	87.5
9	48	3	51	80
10	41	11	52	44
11	42	10	52	10
12	42	11	53	23
13	43	11	54	20
14	44	11	55	87.5
15	48	11	59	0
16	48	11	59	0
17	48	11	59	0

To conclude, in the rabbit and the other mammals investigated so far, the fertilizing ability of spermatozoa in the female declines some time before the capacity for motility. In the foreign environment of the rat uterus, however, rabbit spermatozoa evidently retain the ability to fertilize virtually up to the end of their motile life, which itself is not significantly extended in the rat. It thus becomes apparent that the normal fertile life of rabbit spermatozoa is not a fixed or inherent quality, and that this can be modified within the limits of the motile life, according to the nature of the female environment. The reason for the relative prolongation of the fertilizing ability of rabbit spermatozoa in the rat uterus is not clear. It is possible, however, that the extent of the fertile life of rabbit spermatozoa could be related to the time of capacitation, which must occur before spermatozoa can fertilize an ovum<sup>12,13</sup>. Noyes and Thibault<sup>9</sup> have suggested that some hours after the completion of functional capacitation, a "reversal" (probably better termed "deterioration") of this state may then occur, producing a loss of fertilizing ability in otherwise motile uterine or tubal spermatozoa. It appears from other related investigations, however, that rabbit spermatozoa become only partially capacitated in the uterus of the oestrous rat<sup>14</sup>. Capacitation would not therefore have been completed in the present experiments until 2-4 h after transfer of the spermatozoa from the rat into the rabbit oviduct, and thus only a few hours before the advent of the ova. Thus the prolongation of the fertile life of rabbit spermatozoa residing in the rat uterus might have been a result of the fact that the vulnerable capacitated state was never reached until after the entry of the spermatozoa into the rabbit oviduct and thus only a short while before fertilization.

## A Reversible Inhibitor of Nucleic Acid Synthesis

by

R. A. BUCKNALL

S. B. CARTER

Imperial Chemical Industries Ltd.,  
Pharmaceuticals Division, Research Department,  
Alderley Park, Macclesfield, Cheshire

2-Mercapto-1-( $\beta$ -4-pyridethyl) benzimidazole (MPB) inhibits the incorporation of tritiated uridine and thymidine into RNA and DNA in cell cultures. The effect is readily reversed when the compound is removed, and seems to be connected with the reversible fragmentation of the nucleoli seen when MPB is added to cell cultures.

CARTER found that addition of 2-mercapto-1-( $\beta$ -4-pyridethyl) benzimidazole (MPB) (Fig. 1) to the medium of cultured mammalian cells rapidly caused fragmentation and disappearance of nucleoli. This effect was studied in greater detail using Earle's *L* cells cultured in Eagle's medium containing 8 per cent calf serum. Nucleolar disintegration was visible under phase contrast illumination within 15 min of exposure to 40  $\mu$ g/ml. MPB. The effect was equally rapidly reversed by washing in normal medium and individual nucleoli were restored to their original shape and relative positions. When cells were treated for 24 h with 40  $\mu$ g/ml. MPB, and stained with acridine orange, the characteristic yellow nucleolar fluorescence was totally absent and the orange fluorescence in the cytoplasm very much reduced.

These observations suggested that MPB interferes with nucleic acid metabolism, and this was studied using radioactive precursors.

Stationary cultures of Earle's *L* cells were grown in 4 in.  $\times$  0.5 in. stoppered test-tubes on Eagle's growth medium containing 8 per cent inactivated calf

serum. 24 h before use, the cultures were changed to Eagle's medium containing 0.2 per cent bovine plasma albumin, and used 4–6 days after seeding.

Solutions of MPB were prepared by dissolving the crystalline compound in dimethyl sulphoxide at 1,000 times the maximum required concentration, and making serial dilutions from this stock in Eagle's growth medium. These solutions were added to tissue culture tubes, and the synthesis of nucleic acid and proteins measured by the uptake of radioactive precursors. Tritiated uridine, thymidine and lysine were added to tube cultures at concentrations of 0.33, 0.33 and 0.83  $\mu$ c./ml., respectively, at 37° C. Uptake was stopped after 15 min by washing the cells twice with ice-cold saline and once in 10 per cent perchloric acid. The acid was removed by a further wash with saline, and the cells were stripped from the glass by adding 1 ml. of 0.5 per cent trypsin in water and incubating at 37° C for 15 min. 7 ml. of dioxane scintillator containing 10 per cent naphthalene, 1 per cent PPO and 0.25 per cent POPOP were then added, and the radioactivity measured in a liquid scintillation counter. Results

Fig. 1.

were calculated from the mean count on three tubes and the overall coefficient of variation of the method was found to be 7.9 per cent.

RNA synthesis and DNA synthesis are both rapidly suppressed when *L* cells are treated with 25  $\mu\text{g}/\text{ml}$ . MPB. The full inhibition of approximately 85 per cent is reached in less than 10 min, and RNA and DNA synthesis are affected more or less equally (Fig. 1). In comparison, actinomycin acts principally on RNA synthesis and, at 1  $\mu\text{g}/\text{ml}$ , takes more than an hour to produce the maximum inhibition of 85 per cent. After RNA synthesis is suppressed by actinomycin, the dependent protein synthesis of the cell also declines, primarily because messenger RNA is no longer being produced to activate the ribosomes<sup>1</sup>. The reduction in protein synthesis in *L* cells treated with either actinomycin or MPB is very similar (Fig. 2), which suggests that MPB, like actinomycin, acts principally on RNA synthesis and the effects on protein synthesis are secondary. Increasing the concentration of MPB from 25  $\mu\text{g}/\text{ml}$ . to 100  $\mu\text{g}/\text{ml}$ . does not produce any greater inhibition of protein synthesis, again suggesting that the effect is indirect.

The suppression of nucleic acid synthesis by MPB is proportional to the logarithmic compound concentration up to approximately 50  $\mu\text{g}/\text{ml}$ . (Fig. 3). The departure from linearity beyond this point probably occurs because the compound is incompletely dissolved in the tissue culture medium. Table 1 shows the concentration of MPB required to produce 50 per cent inhibition of RNA or DNA synthesis in a range of tissue culture cells. It appears that RNA and DNA synthesis are suppressed approximately equally, although cells such as HeLa and chick embryo fibroblasts may differ by as much as ten times in their sensitivity to the compound.

Table 1. CONCENTRATION OF MPB ( $\mu\text{g}/\text{ml}$ .) REQUIRED TO REDUCE RNA AND DNA SYNTHESIS BY 50 PER CENT IN A RANGE OF TISSUE CULTURE CELLS

	Primary calf kidney cells	<i>L</i> cells	HeLa	BHK 21	Chick embryo fibroblasts
RNA 50 per cent	7.6	6.3	3.1	7.9	50
DNA 50 per cent	9.3	3.5	2.5	4.0	50

It was noticed that preparations of calf kidney cells varied in their sensitivity to MPB and occasionally required 30–40  $\mu\text{g}/\text{ml}$ . MPB to give 50 per cent inhibition of RNA synthesis. The continuous cell lines, however, maintained a uniform sensitivity over a period of several months.

The inhibition of nucleic acid synthesis by MPB, if not continued for more than a few hours, can be reversed completely by a single change of medium. When *L* cells were treated with 25  $\mu\text{g}/\text{ml}$ . MPB, their DNA and RNA synthesis rapidly fell to 16.5 and 21.2 per cent, respectively, of the normal levels. These low rates were maintained in the presence of the compound and after 2 h were 17.8 and 22.2 per cent, respectively. The compound was removed by changing the medium, and nucleic acid synthesis recovered rapidly (Table 2).

After 20 min in fresh medium the rate of RNA synthesis was almost twice the normal value. This rise probably occurs because RNA precursors accumulated within the cells during the period of inhibition are rapidly utilized. The oscillations between 30 min and 120 min in the rates of both RNA and DNA synthesis probably arise during the re-establishment of various feedback mechanisms.

Table 2. RADIOACTIVITY INCORPORATED BY *L* CELLS AFTER TREATMENT WITH 25  $\mu\text{g}/\text{ml}$ . MPB

	10	20	30	60	120
MPB 25 $\mu\text{g}/\text{ml}$ . for 2 h, medium changed	{ DNA 601 (39.4)	986 (64.5)	1,577 (103)	590 (45.4)	847 (55.6)

RNA = tritiated uridine uptake } Figures in parentheses are percentage of controls.

Fig. 2. Inhibition of RNA (●), DNA (○), and protein synthesis (Δ) in *L* cells by MPB (25  $\mu\text{g}/\text{ml}$ .) and actinomycin D (1  $\mu\text{g}/\text{ml}$ .).

Fig. 3. Inhibition of RNA (●) and DNA (○) synthesis in *L* cells and primary calf kidney cells after 1 h in MPB.

It was interesting to know if MPB inhibited equally the synthesis of high and low molecular weight RNA. *L* cells were grown as monolayers in medical flats and treated with 25  $\mu\text{g}/\text{ml}$ . MPB for 18 h. 1  $\mu\text{C}$ . of tritiated uridine was added to each of fifteen treated flats and also to an equal number of controls. After 4 h at 37° C, all flats were chilled rapidly, drained and the cells scraped from the glass into a *tris* buffer (pH 7.2) containing 0.5 per cent sodium dodecyl sulphate. Impurities were removed by three extractions with phenol at room temperature and RNA precipitated with 2 per cent sodium acetate and 70 per cent ethanol. RNA was reprecipitated three times and finally dissolved in buffer to give approximately 1 mg/ml. A 1 ml. sample was layered on to a 5–20 per cent sucrose density gradient and centrifuged for 18 h at 20,000g. Fractions, each containing ten drops, were collected from the bottom of the tube and their  $OD_{260}$  and

radioactivity were determined. Three molecular species of RNA were recovered with sedimentation coefficients of 27, 18 and 4 S corresponding to high and low molecular weight ribosomal RNA and transfer, or soluble, RNA. The results of one experiment are given in Table 3. The specific activities of the three RNA species from cells treated with MPB expressed as percentages of the corresponding control values are: 27S, 46.7 per cent; 18S, 37.7 per cent; 4S, 54.9 per cent. A second experiment gave similar percentage inhibitions: 27S, 51.2 per cent; 18S, 45.4 per cent; 4S, 38.2 per cent. It seems, therefore, that MPB inhibits the synthesis of ribosomal and transfer RNA equally.

Table 3. SPECIFIC ACTIVITY OF RIBOSOMAL (27S, 18S) AND TRANSFER (4S) RNA ISOLATED FROM *L* CELLS TREATED FOR 18 H WITH 25  $\mu$ g/ml. MPB

25 $\mu$ g/ml. MPB	27S	10.4	250	2.41	46.7
	18S	8.1	125	1.54	37.7
	4S	4.7	200	4.26	54.9

To determine whether or not brief treatment of cells with MPB causes any permanent damage, cells were treated for 4 h with 25  $\mu$ g/ml. of the compound and their growth rate was then compared with untreated cells. As shown in Table 4, *L* cells continue to grow normally following a 4 h exposure to MPB.

Table 4. GROWTH OF *L* CELLS AFTER 4 H TREATMENT WITH 25  $\mu$ g/ml. MPB

	No. of cells per tube	
	Untreated cells	4 h in 25 $\mu$ g/ml. MPB
0 h	$4.35 \times 10^5$	$4.35 \times 10^5$
22 h	$5.15 \times 10^5$	$5.35 \times 10^5$
46 h	$5.81 \times 10^5$	$5.87 \times 10^5$

A consideration of the structure of MPB shows that it bears some resemblance to the nucleic acid ribosides (or deoxyribosides) of adenine and guanine, and also to the dimethylbenzimidazole moiety of vitamin B<sub>12</sub> (Fig. 1). MPB could therefore be acting as an antagonist to the synthesis of nucleic acid purine ribosides or vitamin B<sub>12</sub>. Vitamin B<sub>12</sub> contains adenosyl and dimethylbenzimidazolyl moieties and is involved in a wide range of biochemical pathways, some of which may be important in nucleic acid synthesis. We therefore tried to prevent the inhibition of nucleic acid synthesis in *L* cells by MPB with various mixtures of adenosine, guanosine and dimethylbenzimidazole, but without success (Table 5).

Table 5. SYNTHESIS OF RNA AND DNA BY *L* CELLS TREATED WITH 10  $\mu$ g/ml. MPB

The effects of adding 25  $\mu$ g/ml. adenosine, guanosine, orotic acid and dimethylbenzimidazole (DMB). 10 min counts corrected for background

	RNA		DNA	
	No MPB	MPB 10 $\mu$ g/ml.	No MPB	MPB 10 $\mu$ g/ml.
No additions	24,423	13,270 (54.8)	156,348	58,920 (37.3)
Adenosine	119,868	40,846 (34.2)	142,284	50,728 (35.8)
DMB	19,957	9,915 (50)	124,564	43,876 (35.6)
Adenosine + DMB	100,877	35,292 (35.3)	148,989	45,384 (30.4)
Guanosine	88,711	31,174 (35.2)	121,737	41,862 (34.6)
Guanosine + adenosine	92,620	36,113 (39)	113,982	41,260 (36.4)
Orotic acid	20,724	14,261 (68.2)	149,879	57,712 (37.5)

Figures in parentheses indicate percentage inhibition.

During this work it was noticed that the addition of adenosine, guanosine, or their 5'-phosphates to *L* cell cultures caused a stimulation of RNA synthesis, while the addition of orotic acid or cytidine did not. DNA synthesis was unaffected by the addition of these compounds. Table 5 shows that 25  $\mu$ g/ml. of adenosine caused RNA synthesis to increase five times, and 25  $\mu$ g/ml. of guanosine caused it to increase 2.7 times. In both cases, however, the percentage inhibition produced by 10  $\mu$ g/ml. of MPB is very similar to that found in cells to which no precursors have been added, which suggests that MPB

acts as a non-competitive inhibitor in the overall synthesis of RNA.

The effects of MPB on the phosphorylation of deoxyribosides, and their subsequent incorporation into DNA, were investigated using a kinase and polymerase system isolated from *Escherichia coli*. Tritiated thymidine was converted to thymidine triphosphate with a preparation similar to that of Okazaki and Kornberg<sup>2</sup>. The tritiated thymidine triphosphate was obtained in 90 per cent yield and was used in reaction mixtures containing the remaining three deoxyribonucleoside triphosphates, and a DNA primed DNA polymerase prepared according to Richardson *et al.*<sup>3</sup>. The reaction mixture was incubated at 37° C and after 40 min duplicate 0.1 ml. samples were placed on 1 in.  $\times$  1 in. squares of filter paper which were then washed successively with cold 10 per cent trichloroacetic acid, ethanol and ether. The precipitated material was counted by immersing the papers in a liquid scintillation fluid and counting for 10 min. The radioactive material was identified as DNA by its susceptibility to DNase and resistance to RNase. The results of these experiments are shown in Table 6. It will be seen that 25  $\mu$ g/ml. MPB has no effect on the rate of DNA formation from an equimolar mixture of the four deoxyribonucleoside triphosphates. It was found that DNA synthesis still occurred if individual nucleotides were replaced by the corresponding nucleosides in the polymerase incubation mixture, indicating the presence of nucleoside kinases in the crude polymerase preparation. Thus, with nucleosides in the reaction mixture, the rate of DNA formation is a measure of the nucleoside phosphorylase activity and, using this system, it was shown that MPB had no effect on the conversion of either deoxyadenosine or deoxyguanosine to the corresponding triphosphates. Similarly, MPB was shown to have no effect on the phosphorylation of thymine. Thus, it appears that MPB does not act on the phosphorylation of DNA nucleosides or on the polymerization of nucleotides into DNA. The corresponding RNA systems were not studied. The inhibition of RNA and DNA synthesis by MPB may occur at an earlier stage in purine or pyrimidine metabolism (for example, at the stage of conversion of arylimidazole intermediates to inosine) or MPB may activate an inhibitory feedback mechanism<sup>4,5</sup>.

Table 6. EFFECTS OF MPB ON DNA SYNTHESIS BY AN ISOLATED *E. coli* KINASE/POLYMERASE SYSTEM

Reaction mixture	25 $\mu$ g/ml. MPB	Acid precipitable radioactivity (DNA)
1 dGTP dATP	—	15,699
dCTP dTTP(°H)	+	16,317
2 dG dATP	—	10,375
dCTP dTTP(°H)	+	11,746
3* dGTP dA	—	23,730
dCTP dTTP(°H)	+	27,499

Ten minute counts corrected for background. dATP, deoxyadenosine triphosphate; dGTP, deoxyguanosine triphosphate; dCTP, deoxycytidine triphosphate; dTTP(°H), deoxythymidine triphosphate (tritiated); dA, deoxyadenosine; dG, deoxyguanosine.

\* The reason for the stimulation of DNA synthesis by dA is not known.

Skehel, Hay, Cartwright and Burke have recently suggested (in a personal communication) that MPB acts as a competitive inhibitor in the phosphorylation of uridine to UMP in chick embryo fibroblasts. There may also be an effect on the conversion of UMP to UDP and UTP.

The experimental work for this article was done by Mr. H. Moores. The *E. coli* preparations were kindly supplied by Mr. A. Davies. MPB was first prepared in the laboratories of Midland Tar Distillers, Ltd., and generously supplied for this study.

## Growth Regulatory Effects of Cellular Interaction

by  
HARRY EAGLE  
ELLIOT M. LEVINE

Department of Cell Biology,  
Albert Einstein College of Medicine,  
Bronx, New York

Euploid human fibroblasts and amnion cells showed contact inhibition of growth in monolayers. In mixed cultures the two cell types did not inhibit each other. Neither inhibited the growth of aneuploid epithelial cells. What is the significance of these phenomena with regard to the growth of malignant tumours?

THE marked diminution in the growth rate of human diploid fibroblasts soon after they achieve complete confluency on a glass surface could be related to the contact inhibition of motion as described by Abercrombie *et al.*<sup>1-3</sup>. Some of the molecular events associated with this decreasing growth rate have been described previously<sup>4</sup>. In contrast, most heteroploid human cells achieve much higher populations and mass/unit surface area, continuing to grow at a logarithmic rate well beyond the point of confluency, with the formation of compacted and multilayered sheets. The present communication describes the mutual effects of human diploid and heteroploid cells in mixed culture, measured in terms of cellular proliferation and protein synthesis.

The cell cultures used in the present experiments are listed in Table 1. They include ten strains of euploid fibroblasts from both foetal and postnatal tissues; euploid epithelial amnion cells in primary or secondary passage; three lines of heteroploid human cancer cells (HeLa, *KB*, *HEp2*), and four "spontaneous" transformants deriving from normal tissues (*FL* and *WISH* amnion, liver and conjunctiva), all with highly abnormal karyotypes, including wide differences in chromosome numbers and morphology within the same culture. There were also six cultures of cells with chromosomal aberrations involving one chromosome, three strains of trisomic and hypodiploid skin fibroblasts, and three epithelial cancer cells, one quadriploid (*RPMI* 2650) and two hypodiploid (*C4* and *C33*). All cultures were divided by trypsinization with 0.25 per cent–0.5 per cent 'Difco' 1–250 trypsin in a "minimal" medium free of calcium and magnesium<sup>6</sup>. Trypsinized

cells were shaken off into growth medium supplemented with 10 per cent serum (5 per cent calf and 5 per cent foetal calf) and with the six nutritionally non-essential amino-acids, each at 0.2 mmolar. Cultures of diploid cells were fed with fresh medium two to three times weekly, and divided approximately two- to eight-fold weekly; while heteroploid cells were fed every 1 to 2 days (depending on the amount of cell growth) and divided ten- to eighty-fold weekly. Proteins were determined by a modified Lowry procedure<sup>7</sup>.

*Interaction of euploid human cells in culture.* As illustrated in Table 2 and Fig. 1A, when several different strains of diploid fibroblastic human cells were simultaneously inoculated, the total cell protein and cell number after 5-8 days were usually the same as when a single cell type was planted. Similar results were obtained when a formed monolayer was superinoculated with cells of other strains (Fig. 1B). As shown by over-laying formed monolayers with other cells pre-labelled with  $^{14}\text{C}$ -thymidine, the latter not only adhered to the underlying cellular substrate, but remained adherent during the following 5-8 days of incubation, during which they did not significantly multiply. Ten different diploid fibroblast strains in thirty-three different combinations gave qualitatively similar results (Table 3). One strain (E-196) was, however, significantly less effective than the others in inhibiting the growth of superimposed fibroblasts.

Like the serially propagated diploid fibroblasts, amnion cells in primary culture formed a well defined monolayer of epithelioid cells, after which there was a marked decrease in growth rate. Nevertheless, such monolayers

Table 1. HUMAN CELL CULTURES USED IN PRESENT EXPERIMENTS

Euploid		Minor chromosomal aberrations		Gross chromosomal aberrations

usually failed to inhibit the growth of superimposed diploid fibroblasts, including the amnion-derived fibroblasts which regularly appear in the course of serial passage and eventually overgrow the epithelioid cells (Table 4 and Fig 2A).

**Interaction of euploid and aneuploid human cells in culture.** Fibroblastic skin cultures of trisomic and hypodiploid cells showed contact inhibition of growth, and gave mutual inhibition with euploid fibroblasts (see Table 4). In contrast, a quasi-diploid cancer cell (*RPMI* 2650) and two hypodiploid cancer cells, all epithelial, behaved like those with grossly abnormal karyotypes as described below: they attained much higher population densities than euploid cells in culture, and their growth was either not demonstrably inhibited by contact with the latter, or was inhibited to only a minor degree (see Table 6).

In general, the growth rate of most human cells with marked chromosomal aberrations does not decrease sharply when they form a complete monolayer. Instead,

they continue to grow and form a highly compacted layer in which the number of cells/cm<sup>2</sup> greatly exceeds that attained by euploid cells; and many such cultures form multilayered cell sheets. (With these heteroploid cells, the maximum cell population is determined by unknown factors presumably not directly related to intercellular contact. In some cultures the entire cellular sheet sloughs off the glass; sometimes large areas in the culture become necrotic; and individual cells may come off the multilayered sheet in large numbers.)

The growth of such heteroploid cells was usually not greatly inhibited by contact with diploid cells, whether the latter were epithelial amnion cells (Table 4) or fibroblastic (Tables 5 and 6), and whether the heteroploid cells were inoculated simultaneously with much larger numbers of diploid cells in mixed culture, or superimposed as a few discrete cells on to a completely formed and essentially non-growing layer of diploid cells. Although there was sometimes partial inhibition of the heteroploid cells in

1+5	1,075 (1,168)	1,095 (1,210)	1,325 (1,585)			117 (125+)
1+6	995 (1,192)	1,685 (1,725)	2,225 (2,390)			304 (311)
						334 (344)

Numbers in parentheses indicate theoretical value if there were no mutual inhibition; contrast Table 2.

\* Twenty-four hours after superinoculation of the primary amnion culture. The secondary inocula were all at  $10 \times 10^4$ /ml. ( $2 \times 10^4$ /cm<sup>2</sup>), except for the *FL* cell, which was inoculated at  $6 \times 10^4$ /ml. because of its more rapid growth. The freshly trypsinized primary amnion cells had been planted 8 days previously at  $50 \times 10^4$  cells/ml., only a fraction of which, however, survived.

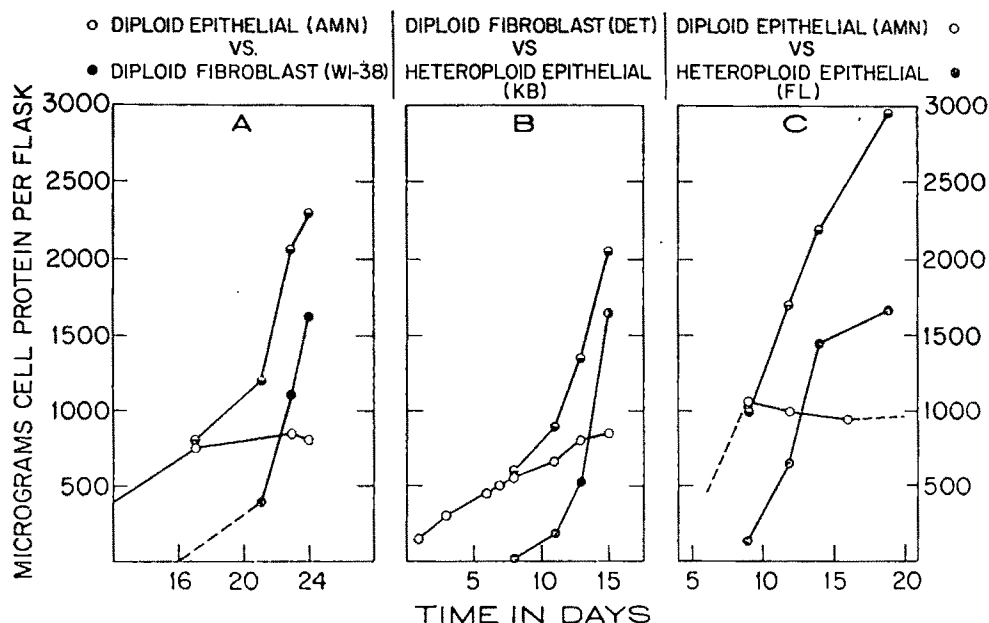

Fig. 2. Lack of mutual growth inhibition between human diploid fibroblasts, diploid epithelial (amnion) cells, and heteroploid cells deriving from normal (*FL*) and cancer (*KB*) tissues. ●—○, Mixed culture.

mixed culture (Table 6), that inhibition requires qualification. Even when the 6 day cumulative growth of heteroploid cells in mixed culture was as little as, for example, 25 per cent of that in the control, the average generation time had been prolonged only from, for example, 24 h to 36 h. It is nevertheless clear from the data of Table 6 that the escape of heteroploid human cells from growth inhibition by euploid cells is not an all or none phenomenon, and that the growth of some heteroploid cells was significantly inhibited by intimate association with some diploid cells (for example, *WI 38* versus *FL*, and *E-196* versus *FL* in Table 6).

In these mixed cultures, the heteroploid cells sometimes grew in compacted and discrete masses instead of the diffusely spread and confluent sheet of the pure culture, indicative of a limitation of their lateral movement, rather than on their growth and division (Fig. 3). Most of these heteroploid cells spread on a glass surface in pure culture and so it seems that their binding affinity to each other is less than that to glass, but greater than their affinity to a diploid monolayer. Published data about the relative mutual adhesiveness of malignant and of non-malignant cells are confusing. Although Coman<sup>17</sup> found cancer cells to have a decreased adhesiveness to each other, malignant mouse and rat cells have recently been reported to form larger aggregates in suspension than their non-malignant

counterparts<sup>18,20</sup>. Not all the heteroploid cells grew in this manner in mixed culture; some separated as they divided to form an "invasive" growth of discrete heteroploid cells which followed the ordered stratification of the diploid fibroblastic monolayer (Fig. 4). This difference in pattern of movement of the heteroploid cells was not, however, associated with differences in the rate of growth. Whether growing as compacted islands or as "invading" cells, many of the heteroploid cell lines grew essentially as rapidly in mixed culture as when they were inoculated alone (see Fig. 2B and Table 6).

Fig. 3. Failure of contact-inhibited diploid human cells to inhibit the growth of heteroploid cells simultaneously inoculated. The fibroblasts were planted at  $40 \times 10^4/\text{ml}$  and  $8 \times 10^4/\text{cm}^2$ , sufficient to form a complete monolayer within a few hours. The heteroploid cells were planted as discrete cells at  $1/40$  of that level. The progressive growth of the heteroploid cells is shown below; the photograph was taken on day 5.

Strain	No. of cells/cm <sup>2</sup> × 10 <sup>4</sup>	μg of cell protein* on day				Heteroploid cells × 10 <sup>4</sup> on day 6
		1	3	5	6	
Diploid alone (Detroit 510)	8	390	458	537	569	—
Heteroploid alone (HeLa)	0.2	—	69	223	459	170
